Package ‘AMR’

October 8, 2020

Version 1.4.0
Date 2020-10-08
Title Antimicrobial Resistance Analysis
Depends R (>= 3.0.0)
Suggests cleaner, curl, dplyr, ggplot2, knitr, microbenchmark, readxl, markdown, rstudioapi, rvest, skimr, testthat, tidyr, xml2
VignetteBuilder knitr, rmarkdown
BugReports https://github.com/msberends/AMR/issues
License GPL-2 | file LICENSE
Encoding UTF-8
LazyData true
RoxygenNote 7.1.1
NeedsCompilation no

ab_from_text

Retrieve antimicrobial drug names and doses from clinical text

Description

Use this function on e.g. clinical texts from health care records. It returns a list with all antimicrobial drugs, doses and forms of administration found in the texts.

Usage

ab_from_text(
  text,
  type = c("drug", "dose", "administration"),
  collapse = NULL,
  translate_ab = FALSE,
  thorough_search = NULL,
  ...
)

Arguments

text text to analyse

type type of property to search for, either "drug", "dose" or "administration", see Examples

collapse character to pass on to paste(...) to only return one character per element of text, see Examples

translate_ab if type = "drug": a column name of the antibiotics data set to translate the antibiotic abbreviations to, using ab_property(). Defaults to FALSE. Using TRUE is equal to using "name".
thorough_search

 logical to indicate whether the input must be extensively searched for misspelling and other faulty input values. Setting this to TRUE will take considerably more time than when using FALSE. At default, it will turn TRUE when all input elements contain a maximum of three words.

... parameters passed on to `as.ab()`

Details

This function is also internally used by `as.ab()`, although it then only searches for the first drug name and will throw a note if more drug names could have been returned.

**Parameter** type:

At default, the function will search for antimicrobial drug names. All text elements will be searched for official names, ATC codes and brand names. As it uses `as.ab()` internally, it will correct for misspelling.

With type = "dose" (or similar, like "dosing", "doses"), all text elements will be searched for numeric values that are higher than 100 and do not resemble years. The output will be numeric. It supports any unit (g, mg, IE, etc.) and multiple values in one clinical text, see Examples.

With type = "administration" (or abbreviations, like "admin", "adm"), all text elements will be searched for a form of drug administration. It supports the following forms (including common abbreviations): buccal, implant, inhalation, instillation, intravenous, nasal, oral, parenteral, rectal, sublingual, transdermal and vaginal. Abbreviations for oral (such as 'po', 'per os') will become "oral", all values for intravenous (such as 'iv', 'intraven') will become "iv". It supports multiple values in one clinical text, see Examples.

**Parameter** collapse:

Without using collapse, this function will return a list. This can be convenient to use e.g. inside a `mutate()`:

```r
df %>% mutate(abx = ab_from_text(clinical_text))
```

The returned AB codes can be transformed to official names, groups, etc. with all `ab_property()` functions like `ab_name()` and `ab_group()`, or by using the translate_ab parameter.

With using collapse, this function will return a character:

```r
df %>% mutate(abx = ab_from_text(clinical_text,collapse = "|"))
```

**Value**

A list, or a character if collapse is not NULL

**Maturing lifecycle**

The lifecycle of this function is maturing. The underlying code of a maturing function has been roughed out, but finer details might still change. Since this function needs wider usage and more extensive testing, you are very welcome to suggest changes at our repository or write us an email (see section 'Contact Us').
Read more on our website!

On our website [https://msberends.github.io/AMR/](https://msberends.github.io/AMR/) you can find a comprehensive tutorial about how to conduct AMR analysis, the complete documentation of all functions and an example analysis using WHONET data. As we would like to better understand the backgrounds and needs of our users, please participate in our survey!

Examples

```r
# mind the bad spelling of amoxicillin in this line, # straight from a true health care record:
ab_from_text("28/03/2020 regular amoxicilliin 500mg po tds")
ab_from_text("500 mg amoxi po and 400mg cipro iv")
ab_from_text("500 mg amoxi po and 400mg cipro iv", type = "dose")
ab_from_text("500 mg amoxi po and 400mg cipro iv", type = "admin")
ab_from_text("500 mg amoxi po and 400mg cipro iv", collapse = ", ")

# if you want to know which antibiotic groups were administered, do e.g.:
abx <- ab_from_text("500 mg amoxi po and 400mg cipro iv")
ab_group(abx[[1]])

if (require("dplyr")) {
  tibble(clinical_text = c("given 400mg cipro and 500 mg amox",
                         "started on doxy iv today")) %>%
  mutate(abx_codes = ab_from_text(clinical_text),
         abx_doses = ab_from_text(clinical_text, type = "doses"),
         abx_admin = ab_from_text(clinical_text, type = "admin"),
         abx_coll = ab_from_text(clinical_text, collapse = "|") ,
         abx_coll_names = ab_from_text(clinical_text,
                        collapse = "|",
                        translate_ab = "name"),
         abx_coll_doses = ab_from_text(clinical_text,
                        type = "doses",
                        collapse = "|") ,
         abx_coll_admin = ab_from_text(clinical_text,
                        type = "admin",
                        collapse = "|") )
}
```

---

**ab_property**  
*Get properties of an antibiotic*

**Description**

Use these functions to return a specific property of an antibiotic from the `antibiotics` data set. All input values will be evaluated internally with `as.ab()`.
Usage

ab_name(x, language = get_locale(), tolower = FALSE, ...)

ab_atc(x, ...)

ab_cid(x, ...)

ab_synonyms(x, ...)

ab_tradenames(x, ...)

ab_group(x, language = get_locale(), ...)

ab_atc_group1(x, language = get_locale(), ...)

ab_atc_group2(x, language = get_locale(), ...)

ab_loinc(x, ...)

ab_ddd(x, administration = "oral", units = FALSE, ...)

ab_info(x, language = get_locale(), ...)

ab_url(x, open = FALSE, ...)

ab_property(x, property = "name", language = get_locale(), ...)

Arguments

x
  any (vector of) text that can be coerced to a valid antibiotic code with as.ab()

language
  language of the returned text, defaults to system language (see get_locale())
  and can also be set with getOption("AMR_locale"). Use language = NULL or
  language = "" to prevent translation.

tolower
  logical to indicate whether the first character of every output should be trans-
  formed to a lower case character. This will lead to e.g. "polymyxin B" and not
  "polymyxin b".

...
  other parameters passed on to as.ab()

administration
  way of administration, either "oral" or "iv"

units
  a logical to indicate whether the units instead of the DDDs itself must be re-
  turned, see Examples

open
  browse the URL using utils::browseURL()

property
  one of the column names of one of the antibiotics data set

Details

All output will be translated where possible.
The function `ab_url()` will return the direct URL to the official WHO website. A warning will be returned if the required ATC code is not available.

**Value**

- An integer in case of `ab_cid()`
- A named list in case of `ab_info()` and multiple `ab_synonyms()`/`ab_tradenames()`
- A double in case of `ab_ddd()`
- A character in all other cases

**Stable lifecycle**

The lifecycle of this function is **stable**. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

ab_group("J01CA01") # Drug group of ampicillins ATC code
ab_loinc("ampicillin") # LOINC codes of ampicillin
ab_name("21066-6") # "Ampicillin" (using LOINC)
ab_name(6249) # "Ampicillin" (using CID)
ab_name("J01CA01") # "Ampicillin" (using ATC)

# spelling from different languages and dyslexia are no problem
ab_atc("ceftriaxon")
ab_atc("cephtriaxone")
ab_atc("cephthiaxone")
ab_atc("seephthriaaksone")

age

---

**Description**

Calculates age in years based on a reference date, which is the system date at default.

**Usage**

age(x, reference = Sys.Date(), exact = FALSE, na.rm = FALSE)
Arguments

- **x**: date(s), will be coerced with `as.POSIXlt()`
- **reference**: reference date(s) (defaults to today), will be coerced with `as.POSIXlt()` and cannot be lower than `x`
- **exact**: a logical to indicate whether age calculation should be exact, i.e. with decimals. It divides the number of days of year-to-date (YTD) of `x` by the number of days in the year of reference (either 365 or 366).
- **na.rm**: a logical to indicate whether missing values should be removed

Value

An integer (no decimals) if `exact = FALSE`, a double (with decimals) otherwise

Stable lifecycle

The lifecycle of this function is **stable**. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

See Also

To split ages into groups, use the **age_groups()** function.

Examples

```r
# 10 random birth dates
df <- data.frame(birth_date = Sys.Date() - runif(10) * 25000)
# add ages
df$age <- age(df$birth_date)
# add exact ages
df$age_exact <- age(df$birth_date, exact = TRUE)

df
```
**age_groups**

**Split ages into age groups**

**Description**

Split ages into age groups defined by the `split_at` parameter. This allows for easier demographic (antimicrobial resistance) analysis.

**Usage**

```r
age_groups(x, split_at = c(12, 25, 55, 75), na.rm = FALSE)
```

**Arguments**

- `x`  
  age, e.g. calculated with `age()`  

- `split_at`  
  values to split `x` at, defaults to age groups 0-11, 12-24, 25-54, 55-74 and 75+. See Details.

- `na.rm`  
  a logical to indicate whether missing values should be removed

**Details**

To split ages, the input for the `split_at` parameter can be:

- A numeric vector. A vector of e.g. `c(10,20)` will split on 0-9, 10-19 and 20+. A value of only 50 will split on 0-49 and 50+. The default is to split on young children (0-11), youth (12-24), young adults (25-54), middle-aged adults (55-74) and elderly (75+).

- A character:
  - "children" or "kids", equivalent of: `c(0,1,2,4,6,13,18)`. This will split on 0, 1, 2-3, 4-5, 6-12, 13-17 and 18+.
  - "elderly" or "seniors", equivalent of: `c(65,75,85)`. This will split on 0-64, 65-74, 75-84, 85+.
  - "fives", equivalent of: `1:20 * 5`. This will split on 0-4, 5-9, 10-14, ..., 90-94, 95-99, 100+.
  - "tens", equivalent of: `1:10 * 10`. This will split on 0-9, 10-19, 20-29, ..., 80-89, 90-99, 100+.

**Value**

Ordered `factor`

**Stable lifecycle**

The **lifecycle** of this function is **stable**. In a stable function, major changes are unlikely. This means that the unlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.
If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

To determine ages, based on one or more reference dates, use the `age()` function.

Examples

ages <- c(3, 8, 16, 54, 31, 76, 101, 43, 21)

# split into 0-49 and 50+
age_groups(ages, 50)

# split into 0-19, 20-49 and 50+
age_groups(ages, c(20, 50))

# split into groups of ten years
age_groups(ages, 1:10 * 10)
age_groups(ages, split_at = "tens")

# split into groups of five years
age_groups(ages, 1:20 * 5)
age_groups(ages, split_at = "fives")

# split specifically for children
age_groups(ages, "children")
# same:
age_groups(ages, c(1, 2, 4, 6, 13, 17))

# resistance of ciprofloxacin per age group
library(dplyr)
example_isolates %>%
  filter_first_isolate() %>%
  filter(mo == as.mo("E. coli")) %>%
  group_by(age_group = age_groups(age)) %>%
  select(age_group, CIP) %>%
  ggplot_rsi(x = "age_group", minimum = 0)
AMR

Description

Welcome to the AMR package.

Details

AMR is a free, open-source and independent R package to simplify the analysis and prediction of Antimicrobial Resistance (AMR) and to work with microbial and antimicrobial data and properties, by using evidence-based methods. Our aim is to provide a standard for clean and reproducible antimicrobial resistance data analysis, that can therefore empower epidemiological analyses to continuously enable surveillance and treatment evaluation in any setting.

After installing this package, R knows ~70,000 distinct microbial species and all ~550 antibiotic, antmycotic and antiviral drugs by name and code (including ATC, EARS-NET, LOINC and SNOMED CT), and knows all about valid R/SI and MIC values. It supports any data format, including WHONET/EARS-Net data.

This package is fully independent of any other R package and works on Windows, macOS and Linux with all versions of R since R-3.0.0 (April 2013). It was designed to work in any setting, including those with very limited resources. It was created for both routine data analysis and academic research at the Faculty of Medical Sciences of the University of Groningen, in collaboration with non-profit organisations Certe Medical Diagnostics and Advice and University Medical Center Groningen. This R package is actively maintained and free software; you can freely use and distribute it for both personal and commercial (but not patent) purposes under the terms of the GNU General Public License version 2.0 (GPL-2), as published by the Free Software Foundation.

This package can be used for:

- Reference for the taxonomy of microorganisms, since the package contains all microbial (sub)species from the Catalogue of Life and List of Prokaryotic names with Standing in Nomenclature
- Interpreting raw MIC and disk diffusion values, based on the latest CLSI or EUCAST guidelines
- Retrieving antimicrobial drug names, doses and forms of administration from clinical health care records
- Determining first isolates to be used for AMR analysis
- Calculating antimicrobial resistance
- Determining multi-drug resistance (MDR) / multi-drug resistant organisms (MDRO)
- Calculating (empirical) susceptibility of both mono therapy and combination therapies
- Predicting future antimicrobial resistance using regression models
- Getting properties for any microorganism (like Gram stain, species, genus or family)
- Getting properties for any antibiotic (like name, code of EARS-Net/ATC/LOINC/PubChem, defined daily dose or trade name)
• Plotting antimicrobial resistance
• Applying EUCAST expert rules
• Getting SNOMED codes of a microorganism, or getting properties of a microorganism based on a SNOMED code
• Getting LOINC codes of an antibiotic, or getting properties of an antibiotic based on a LOINC code
• Machine reading the EUCAST and CLSI guidelines from 2011-2020 to translate MIC values and disk diffusion diameters to R/SI
• Principal component analysis for AMR

Reference data publicly available

All reference data sets (about microorganisms, antibiotics, R/SI interpretation, EUCAST rules, etc.) in this AMR package are publicly and freely available. We continually export our data sets to formats for use in R, SPSS, SAS, Stata and Excel. We also supply flat files that are machine-readable and suitable for input in any software program, such as laboratory information systems. Please find all download links on our website, which is automatically updated with every code change.

antibiotics

Data sets with 557 antimicrobials

Description

Two data sets containing all antibiotics/antimycotics and antivirals. Use as_ab() or one of the ab_property() functions to retrieve values from the antibiotics data set. Three identifiers are included in this data set: an antibiotic ID (ab, primarily used in this package) as defined by WHONET/EARS-Net, an ATC code (atc) as defined by the WHO, and a Compound ID (cid) as found in PubChem. Other properties in this data set are derived from one or more of these codes.
Usage

antibiotics

antivirals

Format

For the antibiotics data set: a data.frame with 455 observations and 14 variables:

- ab
  Antibiotic ID as used in this package (like AMC), using the official EARS-Net (European Antimicrobial Resistance Surveillance Network) codes where available
- atc
  ATC code (Anatomical Therapeutic Chemical) as defined by the WHOCC, like J01CR02
- cid
  Compound ID as found in PubChem
- name
  Official name as used by WHONET/EARS-Net or the WHO
- group
  A short and concise group name, based on WHONET and WHOCC definitions
- atc_group1
  Official pharmacological subgroup (3rd level ATC code) as defined by the WHOCC, like "Macrolides, lincosamides and streptogramins"
- atc_group2
  Official chemical subgroup (4th level ATC code) as defined by the WHOCC, like "Macrolides"
- abbr
  List of abbreviations as used in many countries, also for antibiotic susceptibility testing (AST)
- synonyms
  Synonyms (often trade names) of a drug, as found in PubChem based on their compound ID
- oral_ddd
  Defined Daily Dose (DDD), oral treatment
- oral_units
  Units of oral_ddd
- iv_ddd
  Defined Daily Dose (DDD), parenteral treatment
- iv_units
  Units of iv_ddd
- loinc
  All LOINC codes (Logical Observation Identifiers Names and Codes) associated with the name of the antimicrobial agent. Use ab_loinc() to retrieve them quickly, see ab_property().

For the antivirals data set: a data.frame with 102 observations and 9 variables:

- atc
  ATC code (Anatomical Therapeutic Chemical) as defined by the WHOCC
- cid
  Compound ID as found in PubChem
An object of class `data.frame` with 102 rows and 9 columns.

Details

Properties that are based on an ATC code are only available when an ATC is available. These properties are: `atc_group1`, `atc_group2`, `oral_ddd`, `oral_units`, `iv_ddd` and `iv_units`.

Synonyms (i.e. trade names) are derived from the Compound ID (`cid`) and consequently only available where a CID is available.

Direct download:

These data sets are available as ‘flat files’ for use even without R - you can find the files here:

Files in R format (with preserved data structure) can be found here:

- [https://github.com/msberends/AMR/raw/master/data/antibiotics.rda](https://github.com/msberends/AMR/raw/master/data/antibiotics.rda)
- [https://github.com/msberends/AMR/raw/master/data/antivirals.rda](https://github.com/msberends/AMR/raw/master/data/antivirals.rda)

Reference data publicly available

All reference data sets (about microorganisms, antibiotics, R/SI interpretation, EUCAST rules, etc.) in this AMR package are publicly and freely available. We continually export our data sets to formats for use in R, SPSS, SAS, Stata and Excel. We also supply flat files that are machine-readable and suitable for input in any software program, such as laboratory information systems. Please find all download links on our website, which is automatically updated with every code change.

WHOCC

This package contains **all ~550 antibiotic, antimycotic and antiviral drugs** and their Anatomical Therapeutic Chemical (ATC) codes, ATC groups and Defined Daily Dose (DDD) from the World Health Organization Collaborating Centre for Drug Statistics Methodology (WHOCC, [https://www.whocc.no](http://www.whocc.no)) and the Pharmaceuticals Community Register of the European Commission (http://ec.europa.eu/health/documents/community-register/html/atc.htm).
These have become the gold standard for international drug utilisation monitoring and research. The WHOCC is located in Oslo at the Norwegian Institute of Public Health and funded by the Norwegian government. The European Commission is the executive of the European Union and promotes its general interest.

NOTE: The WHOCC copyright does not allow use for commercial purposes, unlike any other info from this package. See https://www.whocc.no/copyright_disclaimer/.

**antibiotic_class_selectors**

**Antibiotic class selectors**

**Description**

Use these selection helpers inside any function that allows Tidyverse selection helpers, like dplyr::select() or tidyr::pivot_longer(). They help to select the columns of antibiotics that are of a specific antibiotic class, without the need to define the columns or antibiotic abbreviations.

**Usage**

\[ \text{ab_class(ab_class)} \]

\[ \text{aminoglycosides()} \]

\[ \text{carbapenems()} \]

\[ \text{cephalosporins()} \]
antibiotic_class_selectors

cephalosporins_1st()
cephalosporins_2nd()
cephalosporins_3rd()
cephalosporins_4th()
cephalosporins_5th()
fluoroquinolones()
glycopeptides()
macrolides()
penicillins()
tetracyclines()

Arguments

ab_class an antimicrobial class, like "carbapenems". The columns group, atc_group1 and atc_group2 of the antibiotics data set will be searched (case-insensitive) for this value.

Details

All columns will be searched for known antibiotic names, abbreviations, brand names and codes (ATC, EARS-Net, WHO, etc.) in the antibiotics data set. This means that a selector like e.g. aminoglycosides() will pick up column names like 'gen', 'genta', 'J01GB03', 'tobra', 'Tobracin', etc.

N.B. These functions only work if the tidyselect package is installed, that comes with the dplyr package. An error will be thrown if the tidyselect package is not installed, or if the functions are used outside a function that allows Tidyverse selections like select() or pivot_longer().

Reference data publicly available

All reference data sets (about microorganisms, antibiotics, R/SI interpretation, EUCAST rules, etc.) in this AMR package are publicly and freely available. We continually export our data sets to formats for use in R, SPSS, SAS, Stata and Excel. We also supply flat files that are machine-readable and suitable for input in any software program, such as laboratory information systems. Please find all download links on our website, which is automatically updated with every code change.

Read more on our website!

On our website https://msberends.github.io/AMR/ you can find a comprehensive tutorial about how to conduct AMR analysis, the complete documentation of all functions and an example analy-
sis using WHONET data. As we would like to better understand the backgrounds and needs of our users, please participate in our survey!

See Also

`filter_ab_class()` for the `filter()` equivalent.

Examples

```r
if (require("dplyr")) {
  # this will select columns 'IPM' (imipenem) and 'MEM' (meropenem):
  example_isolates %>%
    select(carbapenems())

  # this will select columns 'mo', 'AMK', 'GEN', 'KAN' and 'TOB':
  example_isolates %>%
    select(mo, aminoglycosides())

  # this will select columns 'mo' and all antimycobacterial drugs ('RIF'):
  example_isolates %>%
    select(mo, ab_class("mycobact"))

  # get bug/drug combinations for only macrolides in Gram-positives:
  example_isolates %>%
    filter(mo_gramstain(mo) %like% "pos") %>%
    select(mo, macrolides()) %>%
    bug_drug_combinations() %>%
    format()

  data.frame(some_column = "some_value",
             J01CA01 = "S") %>%  # ATC code of ampicillin
    select(penicillins())  # only the 'J01CA01' column will be selected
}
```

---

as.ab

**Transform input to an antibiotic ID**

**Description**

Use this function to determine the antibiotic code of one or more antibiotics. The data set `antibiotics` will be searched for abbreviations, official names and synonyms (brand names).

**Usage**

```r
as.ab(x, flag_multiple_results = TRUE, info = TRUE, ...)

is.ab(x)
```
Arguments

- **x**: character vector to determine the antibiotic ID
- **flag_multiple_results**: logical to indicate whether a note should be printed to the console that probably more than one antibiotic code or name can be retrieved from a single input value.
- **info**: logical to indicate whether a progress bar should be printed
- **...**: arguments passed on to internal functions

Details

All entries in the *antibiotics* data set have three different identifiers: a human readable EARS-Net code (column `ab`, used by ECDC and WHONET), an ATC code (column `atc`, used by WHO), and a CID code (column `cid`, Compound ID, used by PubChem). The data set contains more than 5,000 official brand names from many different countries, as found in PubChem.

All these properties will be searched for the user input. The `as.ab()` can correct for different forms of misspelling:

- Wrong spelling of drug names (like "tobramicin" or "gentamycin"), which corrects for most audible similarities such as f/ph, x/ks, c/z/s, t/th, etc.
- Too few or too many vowels or consonants
- Switching two characters (like "mreopenem", often the case in clinical data, when doctors typed too fast)
- Digitalised paper records, leaving artefacts like 0/o/O (zero and O’s), B/8, n/r, etc.

Use the `ab_property()` functions to get properties based on the returned antibiotic ID, see Examples.

Value

A character vector with additional class `ab`

Source

World Health Organization (WHO) Collaborating Centre for Drug Statistics Methodology: [https://www.whocc.no/atc_ddd_index/](https://www.whocc.no/atc_ddd_index/)

WHONET 2019 software: [http://www.whonet.org/software.html](http://www.whonet.org/software.html)

Stable lifecycle

The lifecycle of this function is **stable**. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.
WHOCC

These have become the gold standard for international drug utilisation monitoring and research.

The WHOCC is located in Oslo at the Norwegian Institute of Public Health and funded by the Norwegian government. The European Commission is the executive of the European Union and promotes its general interest.

NOTE: The WHOCC copyright does not allow use for commercial purposes, unlike any other info from this package. See https://www.whocc.no/copyright_disclaimer/.

- antibiotics for the data.frame that is being used to determine ATCs
- ab_from_text() for a function to retrieve antimicrobial drugs from clinical text (from health care records)

Examples

# these examples all return "ERY", the ID of erythromycin:
as.ab("J01FA01")
as.ab("J 01 FA 01")
as.ab("Erythromycin")
as.ab("eryt")
as.ab(" eryt 123")
as.ab("ERY")
as.ab("eritromicine") # spelled wrong, yet works
as.ab("Erythrocin") # trade name
as.ab("Romycin") # trade name

# spelling from different languages and dyslexia are no problem
ab_atc("ceftriaxon")
ab_atc("cephtriaxone")  # small spelling error
ab_atc("cephthriaxone")  # or a bit more severe
ab_atc("seephthriaaksone")  # and even this works

# use ab_* functions to get a specific properties (see ?ab_property);
# they use as.ab() internally:
ab_name("J01FA01")  # "Erythromycin"
ab_name("eryt")  # "Erythromycin"

as.rsi()

Examples

# transform existing disk zones to the 'disk' class
library(dplyr)

df <- data.frame(microorganism = "E. coli",
    AMP = 20,
    CIP = 14,
    GEN = 18,
    TOB = 16)
df[, 2:5] <- lapply(df[, 2:5], as.disk)
# same with dplyr:
# df %>% mutate(across(AMP:TOB, as.disk))

# interpret disk values, see ?as.rsi
as.rsi(x = as.disk(18),
    mo = "Strep pneu", # 'mo' will be coerced with as.mo()
    ab = "ampicillin", # and 'ab' with as.ab()
    guideline = "EUCAST")

as.rsi(df)

---

as.mic

Transform input to minimum inhibitory concentrations (MIC)

Description

This transforms a vector to a new class mic, which is an ordered factor with valid minimum inhibitory concentrations (MIC) as levels. Invalid MIC values will be translated as NA with a warning.

Usage

as.mic(x, na.rm = FALSE)

is.mic(x)
as.mic

Arguments

  x  vector
  na.rm  a logical indicating whether missing values should be removed

Details

To interpret MIC values as RSI values, use `as.rsi()` on MIC values. It supports guidelines from EUCAST and CLSI.

Value

  Ordered factor with additional class `mic`

Stable lifecycle

The lifecycle of this function is `stable`. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

  `as.rsi()`

Examples

```r
mic_data <- as.mic(c(">=32", "1.0", "1", "1.00", 8, "<=0.128", "8", "16", "16"))

is.mic(mic_data)

# this can also coerce combined MIC/RSI values:
as.mic("<=0.002; S") # will return <=0.002

# interpret MIC values
as.rsi(x = as.mic(2),
    mo = as.mo("S. pneumoniae"),
    ab = "AMX",
    guideline = "EUCAST")

as.rsi(x = as.mic(4),
    mo = as.mo("S. pneumoniae"),
    ab = "AMX",
    guideline = "EUCAST")
```
as.mo

Transform input to a microorganism ID

Description

Use this function to determine a valid microorganism ID (\textit{mo}). Determination is done using intelligent rules and the complete taxonomic kingdoms Bacteria, Chromista, Protozoa, Archaea and most microbial species from the kingdom Fungi (see Source). The input can be almost anything: a full name (like "\textit{Staphylococcus aureus}"), an abbreviated name (like "\textit{S. aureus}"), an abbreviation known in the field (like "\textit{MRSA}"), or just a genus. Please see \textit{Examples}.

Usage

\begin{verbatim}
as.mo(
  x,
  Becker = FALSE,
  Lancefield = FALSE,
  allow_uncertain = TRUE,
  reference_df = get_mo_source(),
  ignore_pattern =getOption("AMR_ignore_pattern"),
  language = get_locale(),
  ...
)
\end{verbatim}

\textbf{is.mo}(x)
\textbf{mo_failures}()
\textbf{mo_uncertainties}()
\textbf{mo_renamed}()

Arguments

\begin{itemize}
  \item \textbf{x} \hspace{1cm} a character vector or a \texttt{data.frame} with one or two columns
  \item \textbf{Becker} \hspace{1cm} a logical to indicate whether \textit{Staphylococci} should be categorised into coagulase-negative \textit{Staphylococci} ("CoNS") and coagulase-positive \textit{Staphylococci} ("CoPS") instead of their own species, according to Karsten Becker et al. (1,2). Note that this does not include species that were newly named after these publications, like \textit{S. caeli}.
    This excludes \textit{Staphylococcus aureus} at default, use \texttt{Becker = "all"} to also categorise \textit{S. aureus} as "CoPS".
\end{itemize}
Lancefield a logical to indicate whether beta-haemolytic *Streptococci* should be categorised into Lancefield groups instead of their own species, according to Rebecca C. Lancefield (3). These *Streptococci* will be categorised in their first group, e.g. *Streptococcus dysgalactiae* will be group C, although officially it was also categorised into groups G and L.

This excludes *Enterococci* at default (who are in group D), use Lancefield = "all" to also categorise all *Enterococci* as group D.

allow_uncertain a number between 0 (or "none") and 3 (or "all"), or TRUE (= 2) or FALSE (= 0) to indicate whether the input should be checked for less probable results, please see Details

reference_df a data.frame to be used for extra reference when translating x to a valid mo. See set_mo_source() and get_mo_source() to automate the usage of your own codes (e.g. used in your analysis or organisation).

ignore_pattern a regular expression (case-insensitive) of which all matches in x must return NA. This can be convenient to exclude known non-relevant input and can also be set with the option AMR_ignore_pattern, e.g. options(AMR_ignore_pattern = "(not reported|contaminated flora)").

language language to translate text like "no growth", which defaults to the system language (see get_locale())

Details

**General info:**

A microorganism ID from this package (class: mo) is human readable and typically looks like these examples:

<table>
<thead>
<tr>
<th>Code</th>
<th>Full name</th>
</tr>
</thead>
<tbody>
<tr>
<td>B_KLBSL</td>
<td>Klebsiella</td>
</tr>
<tr>
<td>B_KLBSL_PNMN</td>
<td>Klebsiella pneumoniae</td>
</tr>
<tr>
<td>B_KLBSL_PNMN_RHNS</td>
<td>Klebsiella pneumoniae rhinoscleromatis</td>
</tr>
</tbody>
</table>

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| | | | \---> subspecies, a 4-5 letter acronym |
| | | | \----> species, a 4-5 letter acronym |
| | | | \----> genus, a 5-7 letter acronym |
| \----> taxonomic kingdom: A (Archaea), AN (Animalia), B (Bacteria), C (Chromista), F (Fungi), P (Protozoa) |

Values that cannot be coerced will be considered 'unknown' and will get the MO code UNKNOWN. Use the mo_* functions to get properties based on the returned code, see Examples.

The algorithm uses data from the Catalogue of Life (see below) and from one other source (see microorganisms).

The as.mo() function uses several coercion rules for fast and logical results. It assesses the input matching criteria in the following order:
1. Human pathogenic prevalence: the function starts with more prevalent microorganisms, followed by less prevalent ones;
2. Taxonomic kingdom: the function starts with determining Bacteria, then Fungi, then Protozoa, then others;
3. Breakdown of input values to identify possible matches.

This will lead to the effect that e.g. "E. coli" (a microorganism highly prevalent in humans) will return the microbial ID of *Escherichia coli* and not *Entamoeba coli* (a microorganism less prevalent in humans), although the latter would alphabetically come first.

**Coping with uncertain results:**
In addition, the `as.mo()` function can differentiate four levels of uncertainty to guess valid results:
- Uncertainty level 0: no additional rules are applied;
- Uncertainty level 1: allow previously accepted (but now invalid) taxonomic names and minor spelling errors;
- Uncertainty level 2: allow all of level 1, strip values between brackets, inverse the words of the input, strip off text elements from the end keeping at least two elements;
- Uncertainty level 3: allow all of level 1 and 2, strip off text elements from the end, allow any part of a taxonomic name.

The level of uncertainty can be set using the argument `allow_uncertain`. The default is `allow_uncertain = TRUE`, which is equal to uncertainty level 2. Using `allow_uncertain = FALSE` is equal to uncertainty level 0 and will skip all rules. You can also use e.g. `as.mo(...,allow_uncertain = 1)` to only allow up to level 1 uncertainty.

With the default setting (`allow_uncertain = TRUE`, level 2), below examples will lead to valid results:
- "Streptococcus group B (known as S. agalactiae)". The text between brackets will be removed and a warning will be thrown that the result *Streptococcus group B* (B_STRPT_GRP) needs review.
- "S. aureus -please mind: MRSA". The last word will be stripped, after which the function will try to find a match. If it does not, the second last word will be stripped, etc. Again, a warning will be thrown that the result *Staphylococcus aureus* (B_STPHY_AURS) needs review.
- "Fluoroquinolone-resistant Neisseria gonorrhoeae". The first word will be stripped, after which the function will try to find a match. A warning will be thrown that the result *Neisseria gonorrhoeae* (B_NESSR_GNRR) needs review.

There are three helper functions that can be run after using the `as.mo()` function:
- Use `mo_uncertainties()` to get a *data.frame* that prints in a pretty format with all taxonomic names that were guessed. The output contains the matching score for all matches (see *Background on matching score*).
- Use `mo_failures()` to get a *character vector* with all values that could not be coerced to a valid value.
- Use `mo_renamed()` to get a *data.frame* with all values that could be coerced based on old, previously accepted taxonomic names.

**Microbial prevalence of pathogens in humans:**
The intelligent rules consider the prevalence of microorganisms in humans grouped into three groups, which is available as the prevalence columns in the *microorganisms* and *microorganisms.old* data sets. The grouping into human pathogenic prevalence is explained in the section *Matching score for microorganisms* below.
**as.mo**

**Value**

A character vector with additional class `mo`

**Source**

**Stable lifecycle**

The lifecycle of this function is **stable**. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit an error informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

**Matching score for microorganisms**

With ambiguous user input in `as.mo()` and all the `mo_*` functions, the returned results are chosen based on their matching score using `mo_matching_score()`. This matching score `m`, is calculated as:

\[
m_{(x,n)} = \frac{l_n - 0.5 \cdot \min \{ l_n \text{ lev}(x, n) \}}{l_n \cdot p_n \cdot k_n}
\]

where:

- `x` is the user input;
- `n` is a taxonomic name (genus, species, and subspecies);
- `l_n` is the length of `n`;
- `lev` is the Levenshtein distance function, which counts any insertion, deletion and substitution as 1 that is needed to change `x` into `n`;
- `p_n` is the human pathogenic prevalence group of `n`, as described below;
- `k_n` is the taxonomic kingdom of `n`, set as Bacteria = 1, Fungi = 2, Protozoa = 3, Archaea = 4, others = 5.
The grouping into human pathogenic prevalence \((p)\) is based on experience from several microbiological laboratories in the Netherlands in conjunction with international reports on pathogen prevalence. **Group 1** (most prevalent microorganisms) consists of all microorganisms where the taxonomic class is Gammaproteobacteria or where the taxonomic genus is *Enterococcus*, *Staphylococcus* or *Streptococcus*. This group consequently contains all common Gram-negative bacteria, such as *Pseudomonas* and *Legionella* and all species within the order Enterobacterales. **Group 2** consists of all microorganisms where the taxonomic phylum is Proteobacteria, Firmicutes, Actinobacteria or Sarcomastigophora, or where the taxonomic genus is *Absidia*, *Acremonium*, *Actinotignum*, *Alternaria*, *Anaerosalibacter*, *Apophysomyces*, *Arachnia*, *Aspergillus*, *Aureobacterium*, *Aureobasidium*, *Bacteroides*, *Basidiobolus*, *Beauveria*, *Blastocystis*, *Branchamella*, *Calymphatobacterium*, *Candida*, *Capnocytophaga*, *Catabacter*, *Chaetomium*, *Chryseobacterium*, *Chryseomonas*, *Chrysonilia*, *Cladophialophora*, *Cladosporium*, *Conidiobolus*, *Cryptococcus*, *Curvularia*, *Exophiala*, *Exserohilum*, *Flavobacterium*, *Fonsecaea*, *Fusarium*, *Fusobacterium*, *Hendersonula*, *Hypomyces*, *Koserella*, *Lelliottia*, *Leptotrichia*, *Malassezia*, *Mortierella*, *Mucor*, *Mycocentrospora*, *Mycoplasma*, *Nectria*, *Ochroconis*, *Oidiodendron*, *Phoma*, *Piedraia*, *Pithomyces*, *Pityrosporum*, *Prevotella*

*Pseudallescheria*, *Rhizomucor*, *Rhizopus*, *Rhodotorula*, *Scolecosadium*, *Scopulariopsis*, *Scytalidium*, *Sporobolomyces*, *Stachybotrys*, *Stomatococcus*, *Scolecobasidium*, *Scopulariopsis*, *Scytalidium*, *Sporobolomyces*, *Stachybotrys*, *Stomatococcus*, *Treponema*, *Trichoderma*, *Trichophyton*, *Trichosporon*, *Tritirachium* or *Ureaplasma*. **Group 3** consists of all other microorganisms.

All matches are sorted descending on their matching score and for all user input values, the top match will be returned. This will lead to the effect that e.g., "E. coli" will return the microbial ID of *Escherichia coli* \((m = 0.688,\) a highly prevalent microorganism found in humans) and not *Entamoeba coli* \((m = 0.079,\) a less prevalent microorganism in humans), although the latter would alphabetically come first.

**Catalogue of Life**

This package contains the complete taxonomic tree of almost all microorganisms (~70,000 species) from the authoritative and comprehensive Catalogue of Life ([http://www.catalogueoflife.org](http://www.catalogueoflife.org)). The Catalogue of Life is the most comprehensive and authoritative global index of species currently available.

Click here for more information about the included taxa. Check which version of the Catalogue of Life was included in this package with `catalogue_of_life_version()`.

**Reference data publicly available**

All reference data sets (about microorganisms, antibiotics, R/SI interpretation, EUCAST rules, etc.) in this AMR package are publicly and freely available. We continually export our data sets to formats for use in R, SPSS, SAS, Stata and Excel. We also supply flat files that are machine-readable and suitable for input in any software program, such as laboratory information systems. Please find all download links on our website, which is automatically updated with every code change.

microorganisms for the data.frame that is being used to determine ID’s.

The mo_property() functions (like mo_genus().mo_gramstain()) to get properties based on the returned code.

Examples

# These examples all return "B_STPHY_AURS", the ID of S. aureus:
as.mo("sau") # WHONET code
as.mo("stau")
as.mo("STAU")
as.mo("staaur")
as.mo("S. aureus")
as.mo("S aureus")
as.mo("Staphylococcus aureus")
as.mo("Staphylococcus aureus (MRSA)")
as.mo("Zthafilokkoockus oureuz") # handles incorrect spelling
as.mo("MRSA") # Methicillin Resistant S. aureus
as.mo("VISA") # Vancomycin Intermediate S. aureus
as.mo("VRSA") # Vancomycin Resistant S. aureus
as.mo(115329001) # SNOMED CT code

# Dyslexia is no problem - these all work:
as.mo("Ureaplasma urealyticum")
as.mo("Ureaplasma urealyticus")
as.mo("Ureaplasmium urealytica")
as.mo("Ureaplazma urealitycium")
as.mo("Streptococcus group A")
as.mo("GAS") # Group A Streptococci
as.mo("GBS") # Group B Streptococci

as.mo("S. epidermidis") # will remain species: B_STPHY_EPDR
as.mo("S. epidermidis", Becker = TRUE) # will not remain species: B_STPHY_CONS

as.mo("S. pyogenes") # will remain species: B_STRPT_PYGN
as.mo("S. pyogenes", Lancefield = TRUE) # will not remain species: B_STRPT_GRPA

# All mo_* functions use as.mo() internally too (see ?mo_property):
mo_genus("E. coli") # returns "Escherichia"
mo_gramstain("E. coli") # returns "Gram negative"
Description

Interpret minimum inhibitory concentration (MIC) values and disk diffusion diameters according to EUCAST or CLSI, or clean up existing R/Si values. This transforms the input to a new class `rsi`, which is an ordered factor with levels S < I < R. Values that cannot be interpreted will be returned as NA with a warning.

Usage

```r
as.rsi(x, ...)

is.rsi(x)

is.rsi.eligible(x, threshold = 0.05)
```

## S3 method for class 'mic'
```r
as.rsi(
  x,
  mo = NULL,
  ab = deparse(substitute(x)),
  guideline = "EUCAST",
  uti = FALSE,
  conserve_capped_values = FALSE,
  add_intrinsic_resistance = FALSE,
  ...
)
```

## S3 method for class 'disk'
```r
as.rsi(
  x,
  mo = NULL,
  ab = deparse(substitute(x)),
  guideline = "EUCAST",
  uti = FALSE,
  add_intrinsic_resistance = FALSE,
  ...
)
```

## S3 method for class 'data.frame'
```r
as.rsi(
  x,
  ...,
  col_mo = NULL,
  guideline = "EUCAST",
  uti = NULL,
  conserve_capped_values = FALSE,
  add_intrinsic_resistance = FALSE
)
```
Arguments

x  
  vector of values (for class mic: an MIC value in mg/L, for class disk: a disk diffusion radius in millimetres)

...  
  for using on a data.frame: names of columns to apply as.rsi() on (supports tidy selection like AMX:VAN). Otherwise: parameters passed on to methods.

threshold  
  maximum fraction of invalid antimicrobial interpretations of x, please see Examples

mo  
  any (vector of) text that can be coerced to a valid microorganism code with as.mo(), will be determined automatically if the dplyr package is installed

ab  
  any (vector of) text that can be coerced to a valid antimicrobial code with as.ab()

guideline  
  defaults to the latest included EUCAST guideline, see Details for all options

uti  
  (Urinary Tract Infection) A vector with logicals (TRUE or FALSE) to specify whether a UTI specific interpretation from the guideline should be chosen. For using as.rsi() on a data.frame, this can also be a column containing logicals or when left blank, the data set will be search for a 'specimen' and rows containing 'urin' in that column will be regarded isolates from a UTI. See Examples.

conserve_capped_values  
  a logical to indicate that MIC values starting with ">" (but not ">=") must always return "R", and that MIC values starting with "<" (but not "<=") must always return "S"

add_intrinsic_resistance  
  (only useful when using a EUCAST guideline) a logical to indicate whether intrinsic antibiotic resistance must also be considered for applicable bug-drug combinations, meaning that e.g. ampicillin will always return "R" in Klebsiella species. Determination is based on the intrinsic_resistant data set, that itself is based on 'EUCAST Expert Rules, Intrinsic Resistance and Exceptional Phenotypes', version list(version_txt = "v3.1", year = 2016, title = "EUCAST Expert Rules, Intrinsic Resistance and Exceptional Phenotypes") list(version_txt = "v3.2", year = 2020, title = "EUCAST Expert Rules / EUCAST Intrinsic Resistance and Unusual Phenotypes").

col_mo  
  column name of the IDs of the microorganisms (see as.mo()), defaults to the first column of class mo. Values will be coerced using as.mo().

Details

How it works:
The as.rsi() function works in four ways:

1. For cleaning raw / untransformed data. The data will be cleaned to only contain values S, I and R and will try its best to determine this with some intelligence. For example, mixed values with R/SI interpretations and MIC values such as 
"<0.25; S" will be coerced to "S". Combined interpretations for multiple test methods (as seen in laboratory records) such as 
"S; S" will be coerced to "S", but a value like "S; I" will return NA with a warning that the input is unclear.

2. For interpreting minimum inhibitory concentration (MIC) values according to EUCAST or CLSI. You must clean your MIC values first using as.mic(), that also gives your columns
the new data class `mic`. Also, be sure to have a column with microorganism names or codes. It will be found automatically, but can be set manually using the `mo` parameter.

- Using `dplyr`, R/SI interpretation can be done very easily with either:
  ```r
  your_data %>% mutate_if(is.mic, as.rsi)  # until dplyr 1.0.0
  your_data %>% mutate(across(where(is.mic), as.rsi))  # since dplyr 1.0.0
  ```
- Operators like "<=" will be stripped before interpretation. When using `conserve_capped_values = TRUE`, an MIC value of e.g. ">2" will always return "R", even if the breakpoint according to the chosen guideline is ">=4". This is to prevent that capped values from raw laboratory data would not be treated conservatively. The default behaviour (`conserve_capped_values = FALSE`) considers ">2" to be lower than ">=4" and might in this case return "S" or "I".

3. For **interpreting disk diffusion diameters** according to EUCAST or CLSI. You must clean your disk zones first using `as.disk()` , that also gives your columns the new data class `disk`. Also, be sure to have a column with microorganism names or codes. It will be found automatically, but can be set manually using the `mo` parameter.

- Using `dplyr`, R/SI interpretation can be done very easily with either:
  ```r
  your_data %>% mutate_if(is.disk, as.rsi)  # until dplyr 1.0.0
  your_data %>% mutate(across(where(is.disk), as.rsi))  # since dplyr 1.0.0
  ```

4. For **interpreting a complete data set**, with automatic determination of MIC values, disk diffusion diameters, microorganism names or codes, and antimicrobial test results. This is done very simply by running `as.rsi(data)`.

**Supported guidelines:**

**After interpretation:**

After using `as.rsi()`, you can use the `eucast_rules()` defined by EUCAST to (1) apply inferred susceptibility and resistance based on results of other antimicrobials and (2) apply intrinsic resistance based on taxonomic properties of a microorganism.

**Machine readable interpretation guidelines:**

The repository of this package contains a machine readable version of all guidelines. This is a CSV file consisting of 18,650 rows and 10 columns. This file is machine readable, since it contains one row for every unique combination of the test method (MIC or disk diffusion), the antimicrobial agent and the microorganism. This allows for easy implementation of these rules in laboratory information systems (LIS). Note that it only contains interpretation guidelines for humans - interpretation guidelines from CLSI for animals were removed.

**Other:**

The function `is.rsi.eligible()` returns `TRUE` when a columns contains at most 5% invalid antimicrobial interpretations (not S and/or I and/or R), and `FALSE` otherwise. The threshold of 5% can be set with the `threshold` parameter.
Value
Ordered factor with new class `rsi`

Interpretation of R and S/I

In 2019, the European Committee on Antimicrobial Susceptibility Testing (EUCAST) has decided to change the definitions of susceptibility testing categories R and S/I as shown below (https://www.eucast.org/newsstand/).

- **R = Resistant**
  A microorganism is categorised as *Resistant* when there is a high likelihood of therapeutic failure even when there is increased exposure. Exposure is a function of how the mode of administration, dose, dosing interval, infusion time, as well as distribution and excretion of the antimicrobial agent will influence the infecting organism at the site of infection.

- **S = Susceptible**
  A microorganism is categorised as *Susceptible, standard dosing regimen*, when there is a high likelihood of therapeutic success using a standard dosing regimen of the agent.

- **I = Increased exposure, but still susceptible**
  A microorganism is categorised as *Susceptible, Increased exposure* when there is a high likelihood of therapeutic success because exposure to the agent is increased by adjusting the dosing regimen or by its concentration at the site of infection.

This AMR package honours this new insight. Use `susceptibility()` (equal to `proportion_SI()`) to determine antimicrobial susceptibility and `count_susceptible()` (equal to `count_SI()`) to count susceptible isolates.

Stable lifecycle

The lifecycle of this function is **stable**. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

Reference data publicly available

All reference data sets (about microorganisms, antibiotics, R/SI interpretation, EUCAST rules, etc.) in this AMR package are publicly and freely available. We continually export our data sets to formats for use in R, SPSS, SAS, Stata and Excel. We also supply flat files that are machine-readable and suitable for input in any software program, such as laboratory information systems. Please find all download links on our website, which is automatically updated with every code change.

}

---

atc_online_property

Get ATC properties from WHOCC website

Description

Gets data from the WHO to determine properties of an ATC (e.g. an antibiotic), such as the name, defined daily dose (DDD) or standard unit.

Usage

atc_online_property(}
atc_code,  
property,  
administration = "O",  
url = "https://www.whocc.no/atc_ddd_index/?code=%s&showdescription=no",  
url_vet = "https://www.whocc.no/atcvet/atcvet_index/?code=%s&showdescription=no")

atc_online_groups(atc_code, ...)

atc_online_ddd(atc_code, ...)

Arguments

atc_code  
a character or character vector with ATC code(s) of antibiotic(s)

property  
property of an ATC code. Valid values are "ATC", "Name", "DDD", "U" ("unit"),  
"Adm.R", "Note" and groups. For this last option, all hierarchical groups of an  
ATC code will be returned, see Examples.

administration  
type of administration when using property = "Adm.R", see Details

url  
url of website of the WHOCC. The sign %s can be used as a placeholder for  
ATC codes.

url_vet  
url of website of the WHOCC for veterinary medicine. The sign %s can be used  
as a placeholder for ATC_vet codes (that all start with "Q").

...  
parameters to pass on to atc_property

Details

Options for parameter administration:

- "Implant" = Implant
- "Inhal" = Inhalation
- "Instill" = Instillation
- "N" = nasal
- "O" = oral
- "P" = parenteral
- "R" = rectal
- "SL" = sublingual/buccal
- "TD" = transdermal
- "V" = vaginal

Abbreviations of return values when using property = "U" (unit):

- "g" = gram
- "mg" = milligram
- "mcg" = microgram
- "U" = unit
• “TU” = thousand units
• “MU” = million units
• “mmol” = millimole
• “ml” = milliliter (e.g. eyedrops)

N.B. This function requires an internet connection and only works if the following packages are installed: curl, rvest, xml2.

Stable lifecycle

The lifecycle of this function is stable. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

Examples

# oral DDD (Defined Daily Dose) of amoxicillin
atc_online_property(“J01CA04”, “DDD”, “O”)

# parenteral DDD (Defined Daily Dose) of amoxicillin
atc_online_property(“J01CA04”, “DDD”, “P”)

atc_online_property(“J01CA04”, property = “groups”) # search hierarchical groups of amoxicillin
**availability**

*Check availability of columns*

**Description**

Easy check for data availability of all columns in a data set. This makes it easy to get an idea of which antimicrobial combinations can be used for calculation with e.g. `susceptibility()` and `resistance()`.

**Usage**

```r
availability(tbl, width = NULL)
```

**Arguments**

- `tbl` a `data.frame` or list
- `width` number of characters to present the visual availability, defaults to filling the width of the console

**Details**

The function returns a `data.frame` with columns "resistant" and "visual_resistance". The values in that columns are calculated with `resistance()`.

**Value**

`data.frame` with column names of `tbl` as row names

**Stable lifecycle**

The lifecycle of this function is **stable**. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

**Read more on our website!**

**bug_drug_combinations**

Examples

```r
availability(example_isolates)

if (require("dplyr")) {
  example_isolates %>%
    filter(mo == as.mo("E. coli")) %>%
    select_if(is.rsi) %>%
    availability()
}
```

---

**bug_drug_combinations**  
*Determine bug-drug combinations*

Description

Determine antimicrobial resistance (AMR) of all bug-drug combinations in your data set where at least 30 (default) isolates are available per species. Use `format()` on the result to prettify it to a publicable/printable format, see Examples.

Usage

```r
bug_drug_combinations(x, col_mo = NULL, FUN = mo_shortname, ...)
```

## S3 method for class 'bug_drug_combinations'

```r
format(
  x,
  translate_ab = "name (ab, atc)",
  language = get_locale(),
  minimum = 30,
  combine_SI = TRUE,
  combine_IR = FALSE,
  add_ab_group = TRUE,
  remove_intrinsic_resistant = FALSE,
  decimal.mark = getOption("OutDec"),
  big.mark = ifelse(decimal.mark == ",", ",", ",", ","),
  ...
)
```

Arguments

- `x`  
  data with antibiotic columns, such as `amox`, `AMX` and `AMC`
- `col_mo`  
  column name of the IDs of the microorganisms (see `as.mo()`), defaults to the first column of class `mo`. Values will be coerced using `as.mo()`.
- `FUN`  
  the function to call on the `mo` column to transform the microorganism IDs, defaults to `mo_shortname()`
- `...`  
  arguments passed on to `FUN`
translate_ab  a character of length 1 containing column names of the antibiotics data set
language  language of the returned text, defaults to system language (see get_locale()) and can also be set with getOption("AMR_locale"). Use language = NULL or language = "" to prevent translation.
minimum  the minimum allowed number of available (tested) isolates. Any isolate count lower than minimum will return NA with a warning. The default number of 30 isolates is advised by the Clinical and Laboratory Standards Institute (CLSI) as best practice, see Source.
combine_SI  a logical to indicate whether all values of S and I must be merged into one, so the output only consists of S+I vs. R (susceptible vs. resistant). This used to be the parameter combine_IR, but this now follows the redefinition by EUCAST about the interpretation of I (increased exposure) in 2019, see section 'Interpretation of S, I and R' below. Default is TRUE.
combine_IR  logical to indicate whether values R and I should be summed
add_ab_group  logical to indicate where the group of the antimicrobials must be included as a first column
remove_intrinsic_resistant  logical to indicate that rows and columns with 100% resistance for all tested antimicrobials must be removed from the table
decimal.mark  the character to be used to indicate the numeric decimal point.
big.mark  character; if not empty used as mark between every big.interval decimals before (hence big) the decimal point.

Details

The function format() calculates the resistance per bug-drug combination. Use combine_IR = FALSE (default) to test R vs. S+I and combine_IR = TRUE to test R+I vs. S.

Value

The function bug_drug_combinations() returns a data.frame with columns "mo", "ab", "S", "I", "R" and "total".

Stable lifecycle

The lifecycle of this function is stable. In a stable function, major changes are unlikely. This means that the unlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the unlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit an message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

Examples

```r
x <- bug_drug_combinations(example_isolates)

format(x, translate_ab = "name (atc)"

# Use FUN to change to transformation of microorganism codes
bug_drug_combinations(example_isolates,
    FUN = mo_gramstain)

bug_drug_combinations(example_isolates,
    FUN = function(x) ifelse(x == as.mo("E. coli"),
    "E. coli",
    "Others"))
```

description

This package contains the complete taxonomic tree of almost all microorganisms from the authoritative and comprehensive Catalogue of Life.

Catalogue of Life

This package contains the complete taxonomic tree of almost all microorganisms (~70,000 species) from the authoritative and comprehensive Catalogue of Life (http://www.catalogueoflife.org). The Catalogue of Life is the most comprehensive and authoritative global index of species currently available.

Click here for more information about the included taxa. Check which version of the Catalogue of Life was included in this package with catalogue_of_life_version().
Included taxa

Included are:

- All ~61,000 (sub)species from the kingdoms of Archaea, Bacteria, Chromista and Protozoa
- All ~8,500 (sub)species from these orders of the kingdom of Fungi: Eurotiales, Microascales, Mucorales, Onygenales, Pneumocystales, Saccharomycetales, Schizosaccharomycetales and Tremellales. The kingdom of Fungi is a very large taxon with almost 300,000 different (sub)species, of which most are not microbial (but rather macroscopic, like mushrooms). Because of this, not all fungi fit the scope of this package and including everything would tremendously slow down our algorithms too. By only including the aforementioned taxonomic orders, the most relevant fungi are covered (like all species of *Aspergillus*, *Candida*, *Cryptococcus*, *Histplasma*, *Pneumocystis*, *Saccharomyces* and *Trichophyton*).
- All ~150 (sub)species from ~100 other relevant genera from the kingdom of Animalia (like *Strongyloides* and *Taenia*)
- All ~23,000 previously accepted names of all included (sub)species (these were taxonomically renamed)
- The complete taxonomic tree of all included (sub)species: from kingdom to subspecies
- The responsible author(s) and year of scientific publication

The Catalogue of Life (http://www.catalogueoflife.org) is the most comprehensive and authoritative global index of species currently available. It holds essential information on the names, relationships and distributions of over 1.9 million species. The Catalogue of Life is used to support the major biodiversity and conservation information services such as the Global Biodiversity Information Facility (GBIF), Encyclopedia of Life (EoL) and the International Union for Conservation of Nature Red List. It is recognised by the Convention on Biological Diversity as a significant component of the Global Taxonomy Initiative and a contribution to Target 1 of the Global Strategy for Plant Conservation.

The syntax used to transform the original data to a cleansed R format, can be found here: https://github.com/msberends/AMR/blob/master/data-raw/reproduction_of_microorganisms.R

-microorganisms

---

| count | Count available isolates |

**Description**

These functions can be used to count resistant/susceptible microbial isolates. All functions support quasiquotation with pipes, can be used in `summarise()` from the `dplyr` package and also support grouped variables, please see [Examples](#).

`count_resistant()` should be used to count resistant isolates, `count_susceptible()` should be used to count susceptible isolates.

**Usage**

```r
count_resistant(..., only_all_tested = FALSE)
count_susceptible(..., only_all_tested = FALSE)
count_R(..., only_all_tested = FALSE)
count_IR(..., only_all_tested = FALSE)
count_I(..., only_all_tested = FALSE)
count_SI(..., only_all_tested = FALSE)
count_S(..., only_all_tested = FALSE)
```
count_all(..., only_all_tested = FALSE)

n_rsi(..., only_all_tested = FALSE)

count_df(
  data,
  translate_ab = "name",
  language = get_locale(),
  combine_SI = TRUE,
  combine_IR = FALSE
)

Arguments
...

one or more vectors (or columns) with antibiotic interpretations. They will be transformed internally with \texttt{as.rsi()} if needed.

\texttt{only_all_tested}

(for combination therapies, i.e. using more than one variable for ...): a logical to indicate that isolates must be tested for all antibiotics, see section \textit{Combination therapy} below

data

a \texttt{data.frame} containing columns with class \texttt{rsi} (see \texttt{as.rsi()})

\texttt{translate_ab}

a column name of the \texttt{antibiotics} data set to translate the antibiotic abbreviations to, using \texttt{ab_property()}. Use a value

\texttt{language}

language of the returned text, defaults to system language (see \texttt{get_locale()}) and can also be set with \texttt{getOption(\texttt{AMR_locale})}. Use \texttt{language = NULL} or \texttt{language = "} to prevent translation.

\texttt{combine_SI}

a logical to indicate whether all values of S and I must be merged into one, so the output only consists of S+I vs. R (susceptible vs. resistant). This used to be the parameter \texttt{combine_IR}, but this now follows the redefinition by EUCAST about the interpretation of I (increased exposure) in 2019, see section \textit{Interpretation of S, I and R} below. Default is \texttt{TRUE}.

\texttt{combine_IR}

a logical to indicate whether all values of I and R must be merged into one, so the output only consists of S vs. I+R (susceptible vs. non-susceptible). This is outdated, see parameter \texttt{combine_SI}.

Details

These functions are meant to count isolates. Use the \texttt{resistance()/susceptibility()} functions to calculate microbial resistance/susceptibility.

The function \texttt{count_resistant()} is equal to the function \texttt{count_R()}. The function \texttt{count_susceptible()} is equal to the function \texttt{count_SI()}. The function \texttt{n_rsi()} is an alias of \texttt{count_all()}. They can be used to count all available isolates, i.e. where all input antibiotics have an available result (S, I or R). Their use is equal to \texttt{n_distinct()}. Their function is equal to \texttt{count_susceptible(...)} + \texttt{count_resistant(...)}.

The function \texttt{count_df()} takes any variable from \texttt{data} that has an \texttt{rsi} class (created with \texttt{as.rsi()}) and counts the number of S’s, I’s and R’s. It also supports grouped variables. The function \texttt{rsi_df()} works exactly like \texttt{count_df()}, but adds the percentage of S, I and R.
Value

An integer

Stable lifecycle

The lifecycle of this function is stable. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

Interpretation of R and S/I

In 2019, the European Committee on Antimicrobial Susceptibility Testing (EUCAST) has decided to change the definitions of susceptibility testing categories R and S/I as shown below (https://www.eucast.org/newsandr/).

- **R = Resistant**
  A microorganism is categorised as Resistant when there is a high likelihood of therapeutic failure even when there is increased exposure. Exposure is a function of how the mode of administration, dose, dosing interval, infusion time, as well as distribution and excretion of the antimicrobial agent will influence the infecting organism at the site of infection.

- **S = Susceptible**
  A microorganism is categorised as Susceptible, standard dosing regimen, when there is a high likelihood of therapeutic success using a standard dosing regimen of the agent.

- **I = Increased exposure, but still susceptible**
  A microorganism is categorised as Susceptible, Increased exposure when there is a high likelihood of therapeutic success because exposure to the agent is increased by adjusting the dosing regimen or by its concentration at the site of infection.

This AMR package honours this new insight. Use susceptibility() (equal to proportion_SI()) to determine antimicrobial susceptibility and count_susceptible() (equal to count_SI()) to count susceptible isolates.

Combination therapy

When using more than one variable for ... (= combination therapy), use only_all_tested to only count isolates that are tested for all antibiotics/variables that you test them for. See this example for two antibiotics, Drug A and Drug B, about how susceptibility() works to calculate the %SI:

<table>
<thead>
<tr>
<th>Drug A</th>
<th>Drug B</th>
<th>only_all_tested = FALSE</th>
<th>only_all_tested = TRUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>include as numerator</td>
<td>include as denominator</td>
<td>include as numerator</td>
<td>include as denominator</td>
</tr>
<tr>
<td>--------</td>
<td>---------</td>
<td>------------------------</td>
<td>------------------------</td>
</tr>
</tbody>
</table>

Please note that, in combination therapies, for only_all_tested = TRUE applies that:

\[
\text{count}_S() + \text{count}_I() + \text{count}_R() = \text{count}_\text{all}()
\]
\[
\text{proportion}_S() + \text{proportion}_I() + \text{proportion}_R() = 1
\]

and that, in combination therapies, for only_all_tested = FALSE applies that:

\[
\text{count}_S() + \text{count}_I() + \text{count}_R() \geq \text{count}_\text{all}()
\]
\[
\text{proportion}_S() + \text{proportion}_I() + \text{proportion}_R() \geq 1
\]

Using only_all_tested has no impact when only using one antibiotic as input.

count_susceptible(example_isolates$AMX)  # counts "S" and "I"
count_all(example_isolates$AMX)  # counts "S", "I" and "R"

# be more specific
count_S(example_isolates$AMX)
count_SI(example_isolates$AMX)
count_I(example_isolates$AMX)
count_IR(example_isolates$AMX)
count_R(example_isolates$AMX)

# Count all available isolates
```
count_all(example_isolates$AMX)
n_rsi(example_isolates$AMX)

# n_rsi() is an alias of count_all().
# Since it counts all available isolates, you can
# calculate back to count e.g. susceptible isolates.
# These results are the same:
count_susceptible(example_isolates$AMX)
susceptibility(example_isolates$AMX) * n_rsi(example_isolates$AMX)

if (require("dplyr")) {
  example_isolates %>%
    group_by(hospital_id) %>%
    summarise(R = count_R(CIP),
              I = count_I(CIP),
              S = count_S(CIP),
              n1 = count_all(CIP),  # the actual total; sum of all three
              n2 = n_rsi(CIP),  # same - analogous to n_distinct
              total = n())  # NOT the number of tested isolates!

  # Count co-resistance between amoxicillin/clav acid and gentamicin,
  # so we can see that combination therapy does a lot more than mono therapy.
  # Please mind that `susceptibility()` calculates percentages right away instead.
  example_isolates %>% count_susceptible(AMC)  # 1433
  example_isolates %>% count_susceptible(GEN)  # 1399

  example_isolates %>% count_all(AMC)  # 1879
  example_isolates %>% count_all(GEN)  # 1855

  example_isolates %>% count_susceptible(AMC, GEN)  # 1764
  example_isolates %>% count_all(AMC, GEN)  # 1936

  # Get number of S+I vs. R immediately of selected columns
  example_isolates %>%
    select(AMX, CIP) %>%
    count_df(translate = FALSE)

  # It also supports grouping variables
  example_isolates %>%
    select(hospital_id, AMX, CIP) %>%
    group_by(hospital_id) %>%
    count_df(translate = FALSE)
}

---

**eucast_rules**

Apply EUCAST rules
eucast_rules

Description

Apply rules for clinical breakpoints and intrinsic resistance as defined by the European Committee on Antimicrobial Susceptibility Testing (EUCAST, https://eucast.org), see Source.

To improve the interpretation of the antibiogram before EUCAST rules are applied, some non-EUCAST rules can applied at default, see Details.

Usage

eucast_rules(
  x,
  col_mo = NULL,
  info = interactive(),
  rules = getOption("AMR_eucastrules", default = c("breakpoints", "expert")),
  verbose = FALSE,
  version_breakpoints = 10,
  version_expertrules = 3.2,
  ...
)

Arguments

x  data with antibiotic columns, such as amox, AMX and AMC

col_mo column name of the IDs of the microorganisms (see as.mo()), defaults to the first column of class mo. Values will be coerced using as.mo().

info a logical to indicate whether progress should be printed to the console, defaults to only print while in interactive sessions

rules a character vector that specifies which rules should be applied. Must be one or more of "breakpoints", "expert", "other", "all", and defaults to c("breakpoints", "expert"). The default value can be set to another value, e.g. using options(AMR_eucastrules = "all").

verbose a logical to turn Verbose mode on and off (default is off). In Verbose mode, the function does not apply rules to the data, but instead returns a data set in logbook form with extensive info about which rows and columns would be effected and in which way. Using Verbose mode takes a lot more time.

version_breakpoints the version number to use for the EUCAST Clinical Breakpoints guideline. Currently supported: 10.0.

version_expertrules the version number to use for the EUCAST Expert Rules and Intrinsic Resistance guideline. Currently supported: 3.1, 3.2.

... column name of an antibiotic, please see section Antibiotics below

Details

Note: This function does not translate MIC values to RSI values. Use as.rsi() for that.

Note: When ampicillin (AMP, J01CA01) is not available but amoxicillin (AMX, J01CA04) is,
the latter will be used for all rules where there is a dependency on ampicillin. These drugs are interchangeable when it comes to expression of antimicrobial resistance.

**'Other' rules:**

Before further processing, two non-EUCAST rules about drug combinations can be applied to improve the efficacy of the EUCAST rules, and the reliability of your data (analysis). These rules are:

1. A drug with enzyme inhibitor will be set to S if the same drug without enzyme inhibitor is S.
2. A drug without enzyme inhibitor will be set to R if the same drug with enzyme inhibitor is R.

Important examples include amoxicillin and amoxicillin/clavulanic acid, and trimethoprim and trimethoprim/sulfamethoxazole. Needless to say, for these rules to work, both drugs must be available in the data set.

Since these rules are not officially approved by EUCAST, they are not applied at default. To use these rules, include "other" to the rules parameter, or use eucast_rules(. . ., rules = "all").

**Value**

The input of x, possibly with edited values of antibiotics. Or, if verbose = TRUE, a data.frame with all original and new values of the affected bug-drug combinations.

**Antibiotics**

To define antibiotics column names, leave as it is to determine it automatically with guess_ab_col() or input a text (case-insensitive), or use NULL to skip a column (e.g. TIC = NULL to skip ticarcillin). Manually defined but non-existing columns will be skipped with a warning.

The following antibiotics are used for the functions eucast_rules() and mdro(). These are shown below in the format 'name (antimicrobial ID, ATC code)', sorted alphabetically:

Amikacin (AMK, J01GB06), amoxicillin (AMX, J01CA04), amoxicillin/clavulanic acid (AMC, J01CR02), ampicillin (AMP, J01CA01), ampicillin/sulbactam (SAM, J01CR01), avoparcin (AVO, no ATC code), azithromycin (AZM, J01FA10), azlocillin (AZL, J01CA09), aztreonam (ATM, J01DF01), bacampicillin (BAM, J01CA06), benzylpenicillin (PEN, J01CE01), cadazolid (CDZ, J01DD09), capreomycin (CAP, J04AB30), carbenicillin (CRB, J01CA03), carindacillin (CRN, J01CA05), cefacetride (CAC, J01DB10), cefaclor (CEC, J01DC04), cefadroxil (CFR, J01DB05), cefaloridine (RID, J01DB02), cefamandole (MAN, J01DC03), cefatrizine (CTZ, J01DB07), cefazedone (CZD, J01DB06), cefazolin (CZ0, J01DB04), cefdinir (CDR, J01DD15), cefditoren (DIT, J01DD16), cefepime (FEP, J01DE01), cefetamet (CAT, J01DD10), cefixime (CFM, J01DD08), cefmenoxime (CMX, J01DD05), cefmetazole (CMZ, J01DC09), cefodizime (DIZ, J01DD09), cefonicid (CID, J01DC06), cefoperazone (CFP, J01DD12), cefoperazone/sulbactam (CSL, J01DD62), ceforanide (CND, J01DC11), cefotaxime (CTX, J01DD01), cefotetan (CTT, J01DC05), cefotiam (CTF, J01DC07), cefoxitin (FOX, J01DC01), cefoxitin screening (FOX1, no ATC code), cefpirome (CPM, J01DD11), cefpirome (CPD, J01DE02), cefpodoxime (CPD, J01DD13), cefprozil (CPR, J01DC10), cefroxadine (CRD, J01DB11), cefsulodin (CSL, J01DD03), ceftriaxone (CPT, J01DD02), cefazidime (CAZ, J01DD02), cefazidime/clavulanic acid (CCV, J01DD52), ceftazidime (CTD, J01DB12), ceftobutene (CTB, J01DD14), ceftizoxime (CZX, J01DD7), ceftobiprole (BPR, J01DD10), ceftobiprole medocaril (CFM1, J01DD1), ceftolozane/enzyme
inhibitor (CEI, J01D154), ceftriaxone (CRO, J01DD04), cefturoxime (CXM, J01DC02), cephalaxin (LEX, J01DB01), cephalothin (CEP, J01DB03), cephapirin (HAP, J01DB08), cephradine (CED, J01DB09), chloramphenicol (CHL, J01BA01), ciprofloxacin (CIP, J01MA02), clarithromycin (CLR, J01FA05), clindamycin (CLI, J01FF01), colistin (COL, J01XB01), cycloserine (CYC, J04AB01), dalbavancin (DAL, J01XAO4), daptomycin (DAP, J01XO09), dibekacin (DKB, J01GB09), dirithromycin (DIR, J01FA13), doripenem (DOR, J01DH04), doxycycline (DOX, J01AA02), enoxacin (ENX, J01MA04), epicillin (EPC, J01CA07), eravacycline (ERV, J01AA13), ertapenem (ETP, J01DH03), erythromycin (ERY, J01FA01), ethambutol (ETH, J04AK02), fidaxomicin (FXD, no ATC code), fleroxacin (FLE, J01MA08), fluocoxacinilin (FLC, J01CF05), flurithromycin (FLR1, J01FA14), fosfomycin (FOS, J01X001), fusidic acid (FUS, J01XC01), gatifloxacin (GAT, J01MA16), gemifloxacin (GEM, J01MA15), gentamicin (GEN, J01GB03), gentamicin-high (GEH, no ATC code), grepafloxacin (GRX, J01MA11), hetacillin (HET, J01CA18), imipenem (IPM, J01DH51), isepamicin (ISE, J01GB11), isoniazid (INH, J04AC01), josamycin (JOS, J01FA07), kanamycin (KAN, J01GB04), latamoxef (LTM, J01DD06), levofloxacin (LVX, J01MA12), lincomycin (LIN, J01FF02), linezolid (LNZ, J01XX08), lomefloxacin (LOM, J01MA07), loracarbef (LOR, J01DC08), mecillinam (Amoxicillin) (MEC, J01CA11), meropenem (MEM, J01DH02), meropenem/vaborbactam (MEV, J01DH52), metampicillin (MCM, J01CA10), metronidazole (MTR, J01X001), mezlocillin (MEZ, J01CA10), midecamycin (MID, J01FA03), minocycline (MNO, J01AA08), moxifloxacin (MFX, J01MA14), nalidixic acid (NAL, J01MB02), neomycin (NEO, J01GB05), netilmicin (NET, J01GB07), nitrofurantoin (NIT, J01XE01), norfloxacin (NOR, J01MA06), norvancomycin (NVA, no ATC code), novobiocin (NOV, QJ01XX95), ofloxacin (OFX, J01MA01), oleandomycin (OLE, J01FA05), omadacycline (OMC, no ATC code), oritavancin (ORI, J01X005), oxacillin (OXA, J01CF04), pazufloxacin (PAZ, J01MA18), pefloxacin (PEF, J01MA03), phenoxymethylpenicillin (PHN, J01CE02), piperacillin (PIP, J01CA12), piperacillin/tazobactam (TZP, J01CR05), pirlimycin (PRL, no ATC code), pivampicillin (PVM, J01CA02), pivmecillinam (PME, J01CA08), polymyxin B (PBL, J01X002), pristinamycin (PRI, J01FG01), prulifloxacin (PRU, J01MA17), pyrazinamide (PZA, J04AK01), quinupristin/dalfopristin (QDA, J01FG02), ramoplanin (RAM, no ATC code), ribostamycin (RST, J01GB10), rifabutin (RIB, J04AB04), rifampicin (RIF, J04AB02), rifapentine (RFP, J04AB05), rokitamycin (ROK, J01FA12), roxithromycin (RXT, J01FA06), rufloxacin (RLF, J01MA01), sisomicin (J01GF08), sparfloxacin (SPX, J01MA09), spectinomycin (SPT, J01XX04), spiramycin (SPI, J01FA02), streptoduracin (STR, J01GA02), streptomycin (STR1, J01GA01), streptomycin-high (STH, no ATC code), sulbenicillin (SBC, J01CA16), sulfadiazine (SDI, J01EC02), sulfadiazine/trimethoprim (SLT1, J01EE02), sulfamethoxazole (SUL, J01ED01), sulfadimidine (SOM, J01EB03), sulfadimidine/trimethoprim (SLT2, J01EE05), sulfafurazole (SLF, J01EB05), sulfaisodimidine (SLF1, J01EB01), sulfalene (SLF2, J01ED02), sulfamazine (SZO, J01ED09), sulferamerazine (SLF3, J01ED07), sulferamazine/trimethoprim (SLT3, J01EE07), sulfamethizole (SLF4, J01EB02), sulfamethoxazole (SMX, J01EC01), sulfamethoxydiazine (SLF5, J01ED05), sulfametomidine (SLF6, J01ED03), sulfamethoxazole (SLF7, J01ED04), sulfamethrole/trimethoprim (SLT4, J01EE03), sulfamoxole (SLF8, J01EC03), sulfamoxole/trimethoprim (SLT5, J01EE04), sulfanilamide (SLF9, J01EB06), sulfaperin (SLF10, J01ED06), sulfaphenazole (SLF11, J01ED08), sulfapyridine (SLF12, J01EB04), sulfathiazole (SUT, J01EB07), sulfathiourea (SLF13, J01EB08), talampicillin (TAL, J01CA15), tedizolid (TZD, J01XX11), teicoplanin (TEC, J01XA02), teicoplanin-macrometh (TMC, no ATC code), telavancin (TLV, J01X003), telithromycin (TLT, J01FA15), temafloxacin (TMX, J01MA05), temocillin (TEM, J01CA17), tetracycline (TCY, J01AA07), thiacyclaze (THA, no ATC code), ticarcillin (TIC, J01CA13), ticarcillin/clavulanic acid (TCC, J01CR03), tigecycline (TGC, J01AA12), tobramycin (TOB, J01GB01), trimethoprim (TMP, J01EA01), trimethoprim/sulfamethoxazole (SXT, J01EE01), troleandomycin (TRL, J01FA08), trovafloxacin (TVA, J01MA13), vancomycin (VAN, J01X001)
Stable lifecycle

The lifecycle of this function is stable. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

Reference data publicly available

All reference data sets (about microorganisms, antibiotics, R/SI interpretation, EUCAST rules, etc.) in this AMR package are publicly and freely available. We continually export our data sets to formats for use in R, SPSS, SAS, Stata and Excel. We also supply flat files that are machine-readable and suitable for input in any software program, such as laboratory information systems. Please find all download links on our website, which is automatically updated with every code change.

Read more on our website!

On our website https://msberends.github.io/AMR/ you can find a comprehensive tutorial about how to conduct AMR analysis, the complete documentation of all functions and an example analysis using WHONET data. As we would like to better understand the backgrounds and needs of our users, please participate in our survey!

Source

- EUCAST Breakpoint tables for interpretation of MICs and zone diameters. Version 9.0, 2019. (link)

Examples

```r
a <- data.frame(mo = c("Staphylococcus aureus",
"Enterococcus faecalis",
"Escherichia coli",
"Klebsiella pneumoniae",
"Pseudomonas aeruginosa"),
VAN = "-",       # Vancomycin
AMX = "-",       # Amoxicillin
COL = "-",       # Colistin
```

example_isolates
Data set with 2,000 example isolates

Description

A data set containing 2,000 microbial isolates with their full antibiograms. The data set reflects reality and can be used to practice AMR analysis. For examples, please read the tutorial on our website.

Usage

example_isolates

Format

A data frame with 2,000 observations and 49 variables:

- date
date of receipt at the laboratory
• hospital_id
  ID of the hospital, from A to D
• ward_icu
  logical to determine if ward is an intensive care unit
• ward_clinical
  logical to determine if ward is a regular clinical ward
• ward_outpatient
  logical to determine if ward is an outpatient clinic
• age
  age of the patient
• gender
  gender of the patient
• patient_id
  ID of the patient
• mo
  ID of microorganism created with as.mo(), see also microorganisms
• PEN:RIF
  40 different antibiotics with class rsi (see as.rsi()); these column names occur in the antibiotics data set and can be translated with ab_name()
**filter_ab_class**

**Usage**

```r
eexample_isolates_unclean
```

**Format**

A **data.frame** with 3,000 observations and 8 variables:

- **patient_id**
  ID of the patient
- **date**
  date of receipt at the laboratory
- **hospital**
  ID of the hospital, from A to C
- **bacteria**
  info about microorganism that can be transformed with `as.mo()`, see also `microorganisms`
- **AMX:GEN**
  4 different antibiotics that have to be transformed with `as.rsi()`

**Reference data publicly available**

All reference data sets (about microorganisms, antibiotics, R/SI interpretation, EUCAST rules, etc.) in this AMR package are publicly and freely available. We continually export our data sets to formats for use in R, SPSS, SAS, Stata and Excel. We also supply flat files that are machine-readable and suitable for input in any software program, such as laboratory information systems. Please find all download links on our website, which is automatically updated with every code change.

As we would like to better understand the backgrounds and needs of our users, please participate in our survey!

---

**filter_ab_class**

*Filter isolates on result in antimicrobial class*

**Description**

Filter isolates on results in specific antimicrobial classes. This makes it easy to filter on isolates that were tested for e.g. any aminoglycoside, or to filter on carbapenem-resistant isolates without the need to specify the drugs.
filter_ab_class

filter_ab_class(x, ab_class, result = NULL, scope = "any", ...)

Usage

filter_aminoglycosides(x, result = NULL, scope = "any", ...)
filter_carbapenems(x, result = NULL, scope = "any", ...)
filter_cephalosporins(x, result = NULL, scope = "any", ...)
filter_1st_cephalosporins(x, result = NULL, scope = "any", ...)
filter_2nd_cephalosporins(x, result = NULL, scope = "any", ...)
filter_3rd_cephalosporins(x, result = NULL, scope = "any", ...)
filter_4th_cephalosporins(x, result = NULL, scope = "any", ...)
filter_5th_cephalosporins(x, result = NULL, scope = "any", ...)
filter_fluoroquinolones(x, result = NULL, scope = "any", ...)
filter_glycopeptides(x, result = NULL, scope = "any", ...)
filter_macrolides(x, result = NULL, scope = "any", ...)
filter_penicillins(x, result = NULL, scope = "any", ...)
filter_tetracyclines(x, result = NULL, scope = "any", ...)

Arguments

Arguments

x a data set
ab_class an antimicrobial class, like "carbapenems". The columns group, atc_group1 and atc_group2 of the antibiotics data set will be searched (case-insensitive) for this value.
result an antibiotic result: S, I or R (or a combination of more of them)
scope the scope to check which variables to check, can be "any" (default) or "all"
... previously used when this package still depended on the dplyr package, now ignored

Details

All columns of x will be searched for known antibiotic names, abbreviations, brand names and codes (ATC, EARS-Net, WHO, etc.). This means that a filter function like e.g. filter_aminoglycosides() will include column names like 'gen', 'genta', 'J01GB03', 'tobra', 'Tobracin', etc.
Stable lifecycle

The lifecycle of this function is stable. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

See Also

antibiotic_class_selectors() for the select() equivalent.

Examples

filter_aminoglycosides(example_isolates)

if (require("dplyr")) {

  # filter on isolates that have any result for any aminoglycoside
  example_isolates %>% filter_aminoglycosides()
  example_isolates %>% filter_ab_class("aminoglycoside")

  # this is essentially the same as (but without determination of column names):
  example_isolates %>%
    filter_at(.vars = vars(c("GEN", "TOB", "AMK", "KAN")),
      .vars_predicate = any_vars(. %in% c("S", "I", "R")))

  # filter on isolates that show resistance to ANY aminoglycoside
  example_isolates %>% filter_aminoglycosides("R", "any")

  # filter on isolates that show resistance to ALL aminoglycosides
  example_isolates %>% filter_aminoglycosides("R", "all")

  # filter on isolates that show resistance to
  # any aminoglycoside and any fluoroquinolone
  example_isolates %>%
    filter_aminoglycosides("R") %>%
    filter_fluoroquinolones("R")

  # filter on isolates that show resistance to
  # all aminoglycosides and all fluoroquinolones
  example_isolates %>%
    filter_aminoglycosides("R", "all") %>%
    filter_fluoroquinolones("R", "all")

  # with dplyr 1.0.0 and higher (that adds `across()`), this is equal:
  example_isolates %>% filter_carbapenems("R", "all")
  example_isolates %>% filter(across(carbapenems(), ~. == "R"))
first_isolate

Determine first (weighted) isolates

Description

Determine first (weighted) isolates of all microorganisms of every patient per episode and (if needed) per specimen type.

Usage

```r
first_isolate(
  x, 
  col_date = NULL, 
  col_patient_id = NULL, 
  col_mo = NULL, 
  col_testcode = NULL, 
  col_specimen = NULL, 
  col_icu = NULL, 
  col_keyantibiotics = NULL, 
  episode_days = 365, 
  testcodes_exclude = NULL, 
  icu_exclude = FALSE, 
  specimen_group = NULL, 
  type = "keyantibiotics", 
  ignore_I = TRUE, 
  points_threshold = 2, 
  info = interactive(), 
  include_unknown = FALSE, 
  ...
)
```

```r
filter_first_isolate(
  x, 
  col_date = NULL, 
  col_patient_id = NULL, 
  col_mo = NULL, 
  ...
)
```

```r
filter_first_weighted_isolate(
  x, 
  col_date = NULL, 
  col_patient_id = NULL, 
  col_mo = NULL, 
  ...
)
```
col_keyantibiotics = NULL,
...
)

**Arguments**

- **x**: a `data.frame` containing isolates.
- **col_date**: column name of the result date (or date that is was received on the lab), defaults to the first column of with a date class.
- **col_patient_id**: column name of the unique IDs of the patients, defaults to the first column that starts with 'patient' or 'patid' (case insensitive).
- **col_mo**: column name of the IDs of the microorganisms (see `as.mo()`), defaults to the first column of class `mo`. Values will be coerced using `as.mo()`.
- **col_testcode**: column name of the test codes. Use `col_testcode = NULL` to exclude certain test codes (like test codes for screening). In that case `testcodes_exclude` will be ignored.
- **col_specimen**: column name of the specimen type or group.
- **col_icu**: column name of the logicals (TRUE/FALSE) whether a ward or department is an Intensive Care Unit (ICU).
- **col_keyantibiotics**: column name of the key antibiotics to determine first weighted isolates, see `key_antibiotics()`. Defaults to the first column that starts with 'key' followed by 'ab' or 'antibiotics' (case insensitive). Use `col_keyantibiotics = FALSE` to prevent this.
- **episode_days**: episode in days after which a genus/species combination will be determined as 'first isolate' again. The default of 365 days is based on the guideline by CLSI, see Source.
- **testcodes_exclude**: character vector with test codes that should be excluded (case-insensitive).
- **icu_exclude**: logical whether ICU isolates should be excluded (rows with value TRUE in column `col_icu`).
- **specimen_group**: value in column `col_specimen` to filter on.
- **type**: type to determine weighed isolates; can be "keyantibiotics" or "points", see Details.
- **ignore_I**: logical to determine whether antibiotic interpretations with "I" will be ignored when type = "keyantibiotics", see Details.
- **points_threshold**: points until the comparison of key antibiotics will lead to inclusion of an isolate when type = "points", see Details.
- **info**: print progress.
- **include_unknown**: logical to determine whether 'unknown' microorganisms should be included too, i.e. microbial code "UNKNOWN", which defaults to FALSE. For WHONET users, this means that all records with organism code "con" (contamination) will be excluded at default. Isolates with a microbial ID of NA will always be excluded as first isolate.
parameters passed on to the \texttt{first_isolate()} function

\subsection*{Details}

\textbf{WHY THIS IS SO IMPORTANT}

To conduct an analysis of antimicrobial resistance, you should only include the first isolate of every patient per episode (ref). If you would not do this, you could easily get an overestimate or underestimate of the resistance of an antibiotic. Imagine that a patient was admitted with an MRSA and that it was found in 5 different blood cultures the following week. The resistance percentage of oxacillin of all \textit{S. aureus} isolates would be overestimated, because you included this MRSA more than once. It would be selection bias.

All isolates with a microbial ID of \texttt{NA} will be excluded as first isolate.

The functions \texttt{filter_first_isolate()} and \texttt{filter_first_weighted_isolate()} are helper functions to quickly filter on first isolates. The function \texttt{filter_first_isolate()} is essentially equal to either:

\begin{verbatim}
  x[first_isolate(x, ...), ]
  x %>% filter(first_isolate(x, ...))
\end{verbatim}

The function \texttt{filter_first_weighted_isolate()} is essentially equal to:

\begin{verbatim}
  x %>%
  mutate(keyab = key_antibiotics(.)) %>%
  mutate(only_weighted_firsts = first_isolate(x,  
        col_keyantibiotics = "keyab", ...)) %>%
  filter(only_weighted_firsts == TRUE) %>%
  select(-only_weighted_firsts, -keyab)
\end{verbatim}

\subsection*{Value}

A \texttt{logical} vector

\subsection*{Key antibiotics}

There are two ways to determine whether isolates can be included as first weighted isolates which will give generally the same results:

1. Using \texttt{type = "keyantibiotics"} and parameter \texttt{ignore_I}
   Any difference from \texttt{S} to \texttt{R} (or vice versa) will (re)select an isolate as a first weighted isolate. With \texttt{ignore_I = FALSE}, also differences from \texttt{I} to \texttt{S|R} (or vice versa) will lead to this. This is a reliable method and 30-35 times faster than method 2. Read more about this in the \texttt{key_antibiotics()} function.

2. Using \texttt{type = "points"} and parameter \texttt{points_threshold}
   A difference from \texttt{I} to \texttt{S|R} (or vice versa) means 0.5 points, a difference from \texttt{S} to \texttt{R} (or vice versa) means 1 point. When the sum of points exceeds \texttt{points_threshold}, which default to 2, an isolate will be (re)selected as a first weighted isolate.
Stable lifecycle

The lifecycle of this function is stable. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

Methodology of this function is strictly based on:

See Also

`key_antibiotics()`

Examples

```r
# 'example_isolates' is a dataset available in the AMR package.
# See ?example_isolates.

# basic filtering on first isolates
example_isolates[first_isolate(example_isolates), ]

if (require("dplyr")) {
  # Filter on first isolates:
  example_isolates %>%
    mutate(first_isolate = first_isolate(.)) %>%
    filter(first_isolate == TRUE)

  # Short-hand versions:
  example_isolates %>%
    filter_first_isolate()

  example_isolates %>%
    filter_first_weighted_isolate()

  # Now let's see if first isolates matter:
```
A <- example_isolates %>%
group_by(hospital_id) %>%
summarise(count = n_rsi(GEN), # gentamicin availability
          resistance = resistance(GEN)) # gentamicin resistance

B <- example_isolates %>%
filter_first_weighted_isolate() %>% # the 1st isolate filter
group_by(hospital_id) %>%
summarise(count = n_rsi(GEN), # gentamicin availability
          resistance = resistance(GEN)) # gentamicin resistance

# Have a look at A and B.
# B is more reliable because every isolate is counted only once.
# Gentamicin resistance in hospital D appears to be 3.7% higher than
# when you (erroneously) would have used all isolates for analysis.

---

g.test

G-test for Count Data

Description

g.test() performs chi-squared contingency table tests and goodness-of-fit tests, just like chisq.test() but is more reliable (1). A G-test can be used to see whether the number of observations in each category fits a theoretical expectation (called a G-test of goodness-of-fit), or to see whether the proportions of one variable are different for different values of the other variable (called a G-test of independence).

Usage

g.test(x, y = NULL, p = rep(1/length(x), length(x)), rescale.p = FALSE)

Arguments

x a numeric vector or matrix. x and y can also both be factors.

y a numeric vector; ignored if x is a matrix. If x is a factor, y should be a factor of the same length.

p a vector of probabilities of the same length of x. An error is given if any entry of p is negative.

rescale.p a logical scalar; if TRUE then p is rescaled (if necessary) to sum to 1. If rescale.p is FALSE, and p does not sum to 1, an error is given.
Details

If \( x \) is a matrix with one row or column, or if \( x \) is a vector and \( y \) is not given, then a *goodness-of-fit test* is performed (\( x \) is treated as a one-dimensional contingency table). The entries of \( x \) must be non-negative integers. In this case, the hypothesis tested is whether the population probabilities equal those in \( p \), or are all equal if \( p \) is not given.

If \( x \) is a matrix with at least two rows and columns, it is taken as a two-dimensional contingency table: the entries of \( x \) must be non-negative integers. Otherwise, \( x \) and \( y \) must be vectors or factors of the same length; cases with missing values are removed, the objects are coerced to factors, and the contingency table is computed from these. Then Pearson’s chi-squared test is performed of the null hypothesis that the joint distribution of the cell counts in a 2-dimensional contingency table is the product of the row and column marginals.

The p-value is computed from the asymptotic chi-squared distribution of the test statistic.

In the contingency table case simulation is done by random sampling from the set of all contingency tables with given marginals, and works only if the marginals are strictly positive. Note that this is not the usual sampling situation assumed for a chi-squared test (like the \( G \)-test) but rather that for Fisher’s exact test.

In the goodness-of-fit case simulation is done by random sampling from the discrete distribution specified by \( p \), each sample being of size \( n = \text{sum}(x) \). This simulation is done in \( R \) and may be slow.

**G-test of goodness-of-fit (likelihood ratio test):**

Use the \( G \)-test of goodness-of-fit when you have one nominal variable with two or more values (such as male and female, or red, pink and white flowers). You compare the observed counts of numbers of observations in each category with the expected counts, which you calculate using some kind of theoretical expectation (such as a 1:1 sex ratio or a 1:2:1 ratio in a genetic cross).

If the expected number of observations in any category is too small, the \( G \)-test may give inaccurate results, and you should use an exact test instead (\texttt{fisher.test()}).

The \( G \)-test of goodness-of-fit is an alternative to the chi-square test of goodness-of-fit (\texttt{chisq.test()}); each of these tests has some advantages and some disadvantages, and the results of the two tests are usually very similar.

**G-test of independence:**

Use the \( G \)-test of independence when you have two nominal variables, each with two or more possible values. You want to know whether the proportions for one variable are different among values of the other variable.

It is also possible to do a \( G \)-test of independence with more than two nominal variables. For example, Jackson et al. (2013) also had data for children under 3, so you could do an analysis of old vs. young, thigh vs. arm, and reaction vs. no reaction, all analyzed together.

Fisher’s exact test (\texttt{fisher.test()}) is an exact test, where the \( G \)-test is still only an approximation. For any 2x2 table, Fisher’s Exact test may be slower but will still run in seconds, even if the sum of your observations is multiple millions.

The \( G \)-test of independence is an alternative to the chi-square test of independence (\texttt{chisq.test()}), and they will give approximately the same results.

**How the test works:**

Unlike the exact test of goodness-of-fit (\texttt{fisher.test()}), the \( G \)-test does not directly calculate the probability of obtaining the observed results or something more extreme. Instead, like almost
all statistical tests, the $G$-test has an intermediate step; it uses the data to calculate a test statistic that measures how far the observed data are from the null expectation. You then use a mathematical relationship, in this case the chi-square distribution, to estimate the probability of obtaining that value of the test statistic.

The $G$-test uses the log of the ratio of two likelihoods as the test statistic, which is why it is also called a likelihood ratio test or log-likelihood ratio test. The formula to calculate a $G$-statistic is:

$$G = 2 \times \sum (x \times \log(x/E))$$

where $E$ are the expected values. Since this is chi-square distributed, the $p$ value can be calculated in R with:

```R
p <- stats::pchisq(G, df, lower.tail = FALSE)
```

where $df$ are the degrees of freedom.

If there are more than two categories and you want to find out which ones are significantly different from their null expectation, you can use the same method of testing each category vs. the sum of all categories, with the Bonferroni correction. You use $G$-tests for each category, of course.

Value

A list with class "htest" containing the following components:

- `statistic`: the value the chi-squared test statistic.
- `parameter`: the degrees of freedom of the approximate chi-squared distribution of the test statistic, NA if the p-value is computed by Monte Carlo simulation.
- `p.value`: the $p$-value for the test.
- `method`: a character string indicating the type of test performed, and whether Monte Carlo simulation or continuity correction was used.
- `data.name`: a character string giving the name(s) of the data.
- `observed`: the observed counts.
- `expected`: the expected counts under the null hypothesis.
- `residuals`: the Pearson residuals, $(\text{observed} - \text{expected}) / \sqrt{\text{expected}}$.
- `stdres`: standardized residuals, $(\text{observed} - \text{expected}) / \sqrt{\text{V}}$, where $V$ is the residual cell variance (Agresti, 2007, section 2.4.5 for the case where $x$ is a matrix, $n \times p \times (1-p)$ otherwise).

Questioning lifecycle

The lifecycle of this function is questioning. This function might be no longer be optimal approach, or is it questionable whether this function should be in this AMR package at all.

Read more on our website!

On our website https://msberends.github.io/AMR/ you can find a comprehensive tutorial about how to conduct AMR analysis, the complete documentation of all functions and an example analysis using WHONET data. As we would like to better understand the backgrounds and needs of our users, please participate in our survey!
Source

The code for this function is identical to that of \texttt{chisq.test()}, except that:

- The calculation of the statistic was changed to \(2 \ast \text{sum}(x \ast \log(x/E))\)
- Yates' continuity correction was removed as it does not apply to a \(G\)-test
- The possibility to simulate \(p\) values with \texttt{simulate.p.value} was removed

Examples

\begin{verbatim}
# = EXAMPLE 1 =
# Shivrain et al. (2006) crossed clearfield rice (which are resistant
# to the herbicide imazethapyr) with red rice (which are susceptible to
# imazethapyr). They then crossed the hybrid offspring and examined the
# F2 generation, where they found 772 resistant plants, 1611 moderately
# resistant plants, and 737 susceptible plants. If resistance is controlled
# by a single gene with two co-dominant alleles, you would expect a 1:2:1
# ratio.

x <- c(772, 1611, 737)
G <- g.test(x, p = c(1, 2, 1) / 4)
# G$p.value = 0.12574.
# There is no significant difference from a 1:2:1 ratio.
# Meaning: resistance controlled by a single gene with two co-dominant
# alleles, is plausible.

# = EXAMPLE 2 =
# Red crossbills (Loxia curvirostra) have the tip of the upper bill either
# right or left of the lower bill, which helps them extract seeds from pine
# cones. Some have hypothesized that frequency-dependent selection would
# keep the number of right and left-billed birds at a 1:1 ratio. Groth (1992)
# observed 1752 right-billed and 1895 left-billed crossbills.

x <- c(1752, 1895)
G.test(x)
# p = 0.01787343
# There is a significant difference from a 1:1 ratio.
# Meaning: there are significantly more left-billed birds.
\end{verbatim}
ggplot_pca

PCA biplot with ggplot2

Description

Produces a ggplot2 variant of a so-called biplot for PCA (principal component analysis), but is more flexible and more appealing than the base R `biplot()` function.

Usage

```r
ggplot_pca(
  x,
  choices = 1:2,
  scale = TRUE,
  pc.biplot = TRUE,
  labels = NULL,
  labels_textsize = 3,
  labels_text_placement = 1.5,
  groups = NULL,
  ellipse = TRUE,
  ellipse_prob = 0.68,
  ellipse_size = 0.5,
  ellipse_alpha = 0.5,
  points_size = 2,
  points_alpha = 0.25,
  arrows = TRUE,
  arrows_colour = "darkblue",
  arrows_size = 0.5,
  arrows_textsize = 3,
  arrows_textangled = TRUE,
  arrows_alpha = 0.75,
  base_textsize = 10,
  ...
)
```

Arguments

- `x`: an object returned by `pca()`, `prcomp()` or `princomp()`
- `choices`: length 2 vector specifying the components to plot. Only the default is a biplot in the strict sense.
- `scale`: The variables are scaled by `lambda ^ scale` and the observations are scaled by `lambda ^ (1-scale)` where `lambda` are the singular values as computed by `princomp`. Normally `0 <= scale <= 1`, and a warning will be issued if the specified scale is outside this range.
- `pc.biplot`: If true, use what Gabriel (1971) refers to as a "principal component biplot", with `lambda = 1` and observations scaled up by `sqrt(n)` and variables scaled down by...
sqrt(n). Then inner products between variables approximate covariances and
distances between observations approximate Mahalanobis distance.

**labels**

an optional vector of labels for the observations. If set, the labels will be placed
below their respective points. When using the `pca()` function as input for x, this
will be determined automatically based on the attribute `non_numeric_cols`, see
`pca()`.

**labels_textsize**

the size of the text used for the labels

**labels_text_placement**

adjustment factor the placement of the variable names (>=1 means further away
from the arrow head)

**groups**

an optional vector of groups for the labels, with the same length as `labels`. If
set, the points and labels will be coloured according to these groups. When
using the `pca()` function as input for x, this will be determined automatically
based on the attribute `non_numeric_cols`, see `pca()`.

**ellipse**

a logical to indicate whether a normal data ellipse should be drawn for each
group (set with `groups`)

**ellipse_prob**

statistical size of the ellipse in normal probability

**ellipse_size**

the size of the ellipse line

**ellipse_alpha**

the alpha (transparency) of the ellipse line

**points_size**

the size of the points

**points_alpha**

the alpha (transparency) of the points

**arrows**

a logical to indicate whether arrows should be drawn

**arrows_colour**

the colour of the arrow and their text

**arrows_size**

the size (thickness) of the arrow lines

**arrows_textsize**

the size of the text at the end of the arrows

**arrows_textangled**

a logical whether the text at the end of the arrows should be angled

**arrows_alpha**

the alpha (transparency) of the arrows and their text

**base_textsize**

the text size for all plot elements except the labels and arrows

... 

Parameters passed on to functions

**Details**

The colours for labels and points can be changed by adding another scale layer for colour, like
`scale_colour_viridis_d()` or `scale_colour_brewer()`.

**Maturing lifecycle**

The lifecycle of this function is **maturing**. The underlying code of a maturing function has been
roughed out, but finer details might still change. Since this function needs wider usage and more
extensive testing, you are very welcome to suggest changes at our repository or write us an email
(see section ‘Contact Us’).
Source

The ggplot_pca() function is based on the ggbioplot() function from the ggbioplot package by Vince Vu, as found on GitHub: https://github.com/vqv/ggbioplot (retrieved: 2 March 2020, their latest commit: 7325e88; 12 February 2015).

As per their GPL-2 licence that demands documentation of code changes, the changes made based on the source code were:

1. Rewritten code to remove the dependency on packages plyr, scales and grid
2. Parametrised more options, like arrow and ellipse settings
3. Added total amount of explained variance as a caption in the plot
4. Cleaned all syntax based on the lintr package and added integrity checks
5. Updated documentation

Examples

# `example_isolates' is a dataset available in the AMR package.
# See ?example_isolates.

# See ?pca for more info about Principal Component Analysis (PCA).
if (require("dplyr")) {
  pca_model <- example_isolates %>%
    filter(mo_genus(mo) == "Staphylococcus") %>%
    group_by(species = mo_shortname(mo)) %>%
    summarise_if (is.rsi, resistance) %>%
    pca(FLC, AMC, CXM, GEN, TOB, TMP, SXT, CIP, TEC, TCY, ERY)

  # old (base R)
  biplot(pca_model)

  # new
  ggplot_pca(pca_model)

  if (require("ggplot2")) {
    ggplot_pca(pca_model) +
    scale_colour_viridis_d() +
    labs(title = "Title here")
  }
}

Description

Use these functions to create bar plots for antimicrobial resistance analysis. All functions rely on ggplot2 functions.
Usage

```r
ggplot_rsi(
data,  
position = NULL,  
x = "antibiotic",  
fill = "interpretation",  
facet = NULL,  
breaks = seq(0, 1, 0.1),  
limits = NULL,  
translate_ab = "name",  
combine_SI = TRUE,  
combine_IR = FALSE,  
minimum = 30,  
language = get_locale(),  
nrow = NULL,  
colours = c(S = "#61a8ff", SI = "#61a8ff", I = "#61f7ff", IR = "#ff6961", R = "#ff6961"),  
datalabels = TRUE,  
datalabels.size = 2.5,  
datalabels.colour = "gray15",  
title = NULL,  
subtitle = NULL,  
caption = NULL,  
x.title = "Antimicrobial",  
y.title = "Proportion",  
...  
)
```

```r
geom_rsi(
position = NULL,  
x = c("antibiotic", "interpretation"),  
fill = "interpretation",  
translate_ab = "name",  
minimum = 30,  
language = get_locale(),  
combine_SI = TRUE,  
combine_IR = FALSE,  
...  
)
```

```r
facet_rsi(facet = c("interpretation", "antibiotic"), nrow = NULL)
```

```r
scale_y_percent(breaks = seq(0, 1, 0.1), limits = NULL)
```

```r
scale_rsi_colours(
colours = c(S = "#61a8ff", SI = "#61a8ff", I = "#61f7ff", IR = "#ff6961", R = "#ff6961")
)
```
theme_rsi()

labels_rsi_count(
    position = NULL,
    x = "antibiotic",
    translate_ab = "name",
    minimum = 30,
    language = get_locale(),
    combine_SI = TRUE,
    combine_IR = FALSE,
    datalabels.size = 3,
    datalabels.colour = "gray15"
)

Arguments

data a data.frame with column(s) of class rsi (see as.rsi())

position position adjustment of bars, either "fill", "stack" or "dodge"

x variable to show on x axis, either "antibiotic" (default) or "interpretation"
or a grouping variable

fill variable to categorise using the plots legend, either "antibiotic" (default) or "interpretation"or a grouping variable

facet variable to split plots by, either "interpretation" (default) or "antibiotic"or a grouping variable

breaks numeric vector of positions

limits numeric vector of length two providing limits of the scale, use NA to refer to theexisting minimum or maximum

translate_ab a column name of the antibiotics data set to translate the antibiotic abbreviations
to, using ab_property(). Use a value

combine_SI a logical to indicate whether all values of S and I must be merged into one, so theoutput only consists of S+I vs. R (susceptible vs. resistant). This used to be theparameter combine_IR, but this now follows the redefinition by EUCAST about theinterpretation of I (increased exposure) in 2019, see section 'Interpretation ofS, I and R' below. Default is TRUE.

combine_IR a logical to indicate whether all values of I and R must be merged into one, so theoutput only consists of S vs. I+R (susceptible vs. non-susceptible). This isoutdated, see parameter combine_SI.

minimum the minimum allowed number of available (tested) isolates. Any isolate countlower than minimum will return NA with a warning. The default number of 30isolates is advised by the Clinical and Laboratory Standards Institute (CLSI) asbest practice, see Source.

language language of the returned text, defaults to system language (see get_locale())and can also be set with getOption("AMR_locale"). Use language = NULL orlanguage = "" to prevent translation.
## ggplot_rsi

This function is a wrapper around several plotting functions to visualize the results of an AMR analysis. The input data should have the class `rsi`.

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nrow</td>
<td>(when using facet) number of rows</td>
</tr>
<tr>
<td>colours</td>
<td>a named vector with colours for the bars. The names must be one or more of: S, SI, I, IR, R or be FALSE to use default ggplot2::ggplot() colours.</td>
</tr>
<tr>
<td>datalabels</td>
<td>show datalabels using labels_rsi_count()</td>
</tr>
<tr>
<td>datalabels.size</td>
<td>size of the datalabels</td>
</tr>
<tr>
<td>datalabels.colour</td>
<td>colour of the datalabels</td>
</tr>
<tr>
<td>title</td>
<td>text to show as title of the plot</td>
</tr>
<tr>
<td>subtitle</td>
<td>text to show as subtitle of the plot</td>
</tr>
<tr>
<td>caption</td>
<td>text to show as caption of the plot</td>
</tr>
<tr>
<td>x.title</td>
<td>text to show as x axis description</td>
</tr>
<tr>
<td>y.title</td>
<td>text to show as y axis description</td>
</tr>
<tr>
<td>...</td>
<td>other parameters passed on to geom_rsi()</td>
</tr>
</tbody>
</table>

### Details

At default, the names of antibiotics will be shown on the plots using ab_name(). This can be set with the translate_ab parameter. See count_df().

The functions:

- **geom_rsi()** will take any variable from the data that has an rsi class (created with as.rsi()) using rsi_df() and will plot bars with the percentage R, I and S. The default behaviour is to have the bars stacked and to have the different antibiotics on the x axis.
- **facet_rsi()** creates 2d plots (at default based on S/I/R) using ggplot2::facet_wrap().
- **scale_y_percent()** transforms the y axis to a 0 to 100% range using ggplot2::scale_y_continuous().
- **scale_rsi_colours()** sets colours to the bars: pastel blue for S, pastel turquoise for I and pastel red for R, using ggplot2::scale_fill_manual().
- **theme_rsi()** is a [ggplot2 theme](https://msberends.github.io/AMR/) with minimal distraction.
- **labels_rsi_count()** print datalabels on the bars with percentage and amount of isolates using ggplot2::geom_text().
- **ggplot_rsi()** is a wrapper around all above functions that uses data as first input. This makes it possible to use this function after a pipe (%>%). See Examples.

### Maturing lifecycle

The lifecycle of this function is maturing. The unlying code of a maturing function has been roughed out, but finer details might still change. Since this function needs wider usage and more extensive testing, you are very welcome to suggest changes at our repository or write us an email (see section 'Contact Us').

### Read more on our website!

On our website [https://msberends.github.io/AMR/](https://msberends.github.io/AMR/) you can find a comprehensive tutorial about how to conduct AMR analysis, the complete documentation of all functions and an example analysis using WHONET data. As we would like to better understand the backgrounds and needs of our users, please participate in our survey!
Examples

if (require("ggplot2") & require("dplyr")) {

# get antimicrobial results for drugs against a UTI:
ggplot(example_isolates %>% select(AMX, NIT, FOS, TMP, CIP)) +
  geom_rsi()

# prettify the plot using some additional functions:
df <- example_isolates %>% select(AMX, NIT, FOS, TMP, CIP)

  ggplot(df) +
  geom_rsi() +
  scale_y_percent() +
  scale_rsi_colours() +
  labels_rsi_count() +
  theme_rsi()

# or better yet, simplify this using the wrapper function - a single command:
exemplar %>%
  select(AMX, NIT, FOS, TMP, CIP) %>%
  ggplot_rsi()

# get only proportions and no counts:
exemplar %>%
  select(AMX, NIT, FOS, TMP, CIP) %>%
  ggplot_rsi(datalabels = FALSE)

# add other ggplot2 parameters as you like:
exemplar %>%
  select(AMX, NIT, FOS, TMP, CIP) %>%
  ggplot_rsi(width = 0.5,
            colour = "black",
            size = 1,
            linetype = 2,
            alpha = 0.25)

e.xemplar %>%
  select(AMX) %>%
  ggplot_rsi(colours = c(SI = "yellow"))

# resistance of ciprofloxacin per age group
exemplar %>%
  mutate(first_isolate = first_isolate(.)) %>%
  filter(first_isolate == TRUE,
         mo == as.mo("E. coli")) %>%
# "age_groups" is also a function of this AMR package:
group_by(age_group = age_groups(age)) %>%
  select(age_group,
         CIP) %>%
ggplot_rsi(x = "age_group")

# for colourblind mode, use divergent colours from the viridis package:
example_isolates %>%
  select(AMX, NIT, FOS, TMP, CIP) %>%
  ggplot_rsi() +
  scale_fill_viridis_d()
# a shorter version which also adjusts data label colours:
example_isolates %>%
  select(AMX, NIT, FOS, TMP, CIP) %>%
  ggplot_rsi(colours = FALSE)

# it also supports groups (don't forget to use the group var on 'x' or 'facet'):
example_isolates %>%
  select(hospital_id, AMX, NIT, FOS, TMP, CIP) %>%
  group_by(hospital_id) %>%
  ggplot_rsi(x = "hospital_id",
             facet = "antibiotic",
             nrow = 1,
              title = "AMR of Anti-UTI Drugs Per Hospital",
             x.title = "Hospital",
             datalabels = FALSE)

---

**guess_ab_col**

**Guess antibiotic column**

**Description**

This tries to find a column name in a data set based on information from the `antibiotics` data set. Also supports WHONET abbreviations.

**Usage**

```r
guess_ab_col(x = NULL, search_string = NULL, verbose = FALSE)
```

**Arguments**

- `x`: a data.frame
- `search_string`: a text to search `x` for, will be checked with `as.ab()` if this value is not a column in `x`
- `verbose`: a logical to indicate whether additional info should be printed

**Details**

You can look for an antibiotic (trade) name or abbreviation and it will search `x` and the `antibiotics` data set for any column containing a name or code of that antibiotic. **Longer column names take precedence over shorter column names.**
Value

A column name of x, or NULL when no result is found.

Stable lifecycle

The lifecycle of this function is stable. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

# [1] "tetr"

# WHONET codes
df <- data.frame(AMP_ND10 = "R",
                 AMC_ED20 = "S")

guess_ab_col(df, "ampicillin")
# [1] "AMP_ND10"
guess_ab_col(df, "J01CR02")
# [1] "AMC_ED20"
guess_ab_col(df, as.ab("augmentin"))
# [1] "AMC_ED20"

# Longer names take precedence:
df <- data.frame(AMP_ED2 = "S",
                 AMP_ED20 = "S")

guess_ab_col(df, "ampicillin")
# [1] "AMP_ED20"
**intrinsic_resistant**  
*Data set with bacterial intrinsic resistance*

**Description**

Data set containing defined intrinsic resistance by EUCAST of all bug-drug combinations.

**Usage**

`intrinsic_resistant`

**Format**

A data frame with 93,892 observations and 2 variables:

- `microorganism`
  Name of the microorganism
- `antibiotic`
  Name of the antibiotic drug

**Details**

The repository of this AMR package contains a file comprising this exact data set: [https://github.com/msberends/AMR/blob/master/data-raw/intrinsic_resistant.txt](https://github.com/msberends/AMR/blob/master/data-raw/intrinsic_resistant.txt). This file allows for machine reading EUCAST guidelines about intrinsic resistance, which is almost impossible with the Excel and PDF files distributed by EUCAST. The file is updated automatically.

This data set is based on 'EUCAST Expert Rules / EUCAST Intrinsic Resistance and Unusual Phenotypes', v3.2 from 2020.

**Reference data publicly available**

All reference data sets (about microorganisms, antibiotics, R/SI interpretation, EUCAST rules, etc.) in this AMR package are publicly and freely available. We continually export our data sets to formats for use in R, SPSS, SAS, Stata and Excel. We also supply flat files that are machine-readable and suitable for input in any software program, such as laboratory information systems. Please find all download links on our website, which is automatically updated with every code change.

**Read more on our website!**

On our website [https://msberends.github.io/AMR/](https://msberends.github.io/AMR/) you can find a comprehensive tutorial about how to conduct AMR analysis, the complete documentation of all functions and an example analysis using WHONET data. As we would like to better understand the backgrounds and needs of our users, please participate in our survey!
Examples

```r
if (require("dplyr")) {
  intrinsic_resistant %>%
    filter(antibiotic == "Vancomycin", microorganism %like% "Enterococcus") %>%
    pull(microorganism)
  # [1] "Enterococcus casseliflavus" "Enterococcus gallinarum"
}
```

---

**join**

*Join microorganisms to a data set*

**Description**

Join the data set **microorganisms** easily to an existing table or character vector.

**Usage**

```r
inner_join_microorganisms(x, by = NULL, suffix = c("2", ""), ...)
left_join_microorganisms(x, by = NULL, suffix = c("2", ""), ...)
right_join_microorganisms(x, by = NULL, suffix = c("2", ""), ...)
full_join_microorganisms(x, by = NULL, suffix = c("2", ""), ...)
semi_join_microorganisms(x, by = NULL, ...)
anti_join_microorganisms(x, by = NULL, ...)
```

**Arguments**

- `x`  
  existing table to join, or character vector
- `by`  
  a variable to join by - if left empty will search for a column with class `mo` (created with `as.mo()`) or will be "mo" if that column name exists in `x`, could otherwise be a column name of `x` with values that exist in `microorganisms$mo` (like `by = "bacteria_id"`), or another column in `microorganisms` (but then it should be named, like `by = c("bacteria_id" = "fullname")`)
- `suffix`  
  if there are non-joined duplicate variables in `x` and `y`, these suffixes will be added to the output to disambiguate them. Should be a character vector of length 2.
- `...`  
  ignored

**Details**

**Note:** As opposed to the `join()` functions of dplyr, character vectors are supported and at default existing columns will get a suffix "2" and the newly joined columns will not get a suffix.

If the dplyr package is installed, their join functions will be used. Otherwise, the much slower `merge()` function from base R will be used.
Stable lifecycle

The lifecycle of this function is stable. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

As we would like to better understand the backgrounds and needs of our users, please participate in our survey!

Examples

left_join_microorganisms(as.mo("K. pneumoniae"))
left_join_microorganisms("B_KLBSL_PNE")

if (require("dplyr")) {
  example_isolates %>%
    left_join_microorganisms() %>%
    colnames()
    df <- data.frame(date = seq(from = as.Date("2018-01-01"),
                   to = as.Date("2018-01-07"),
                   by = 1),
                   bacteria = as.mo(c("S. aureus", "MRSA", "MSSA", "STAAUR",
                             "E. coli", "E. coli", "E. coli")),
                   stringsAsFactors = FALSE)
    colnames(df)
    df_joined <- left_join_microorganisms(df, "bacteria")
    colnames(df_joined)
}

key_antibiotics

Key antibiotics for first weighted isolates

Description

These function can be used to determine first isolates (see first_isolate()). Using key antibiotics to determine first isolates is more reliable than without key antibiotics. These selected isolates will then be called first weighted isolates.
key_antibiotics

Usage

key_antibiotics(
  x,
  col_mo = NULL,
  universal_1 = guess_ab_col(x, "amoxicillin"),
  universal_2 = guess_ab_col(x, "amoxicillin/clavulanic acid"),
  universal_3 = guess_ab_col(x, "cefuroxime"),
  universal_4 = guess_ab_col(x, "piperacillin/tazobactam"),
  universal_5 = guess_ab_col(x, "ciprofloxacin"),
  universal_6 = guess_ab_col(x, "trimethoprim/sulfamethoxazole"),
  GramPos_1 = guess_ab_col(x, "vancomycin"),
  GramPos_2 = guess_ab_col(x, "teicoplanin"),
  GramPos_3 = guess_ab_col(x, "tetracycline"),
  GramPos_4 = guess_ab_col(x, "erythromycin"),
  GramPos_5 = guess_ab_col(x, "oxacillin"),
  GramPos_6 = guess_ab_col(x, "rifampin"),
  GramNeg_1 = guess_ab_col(x, "gentamicin"),
  GramNeg_2 = guess_ab_col(x, "tobramycin"),
  GramNeg_3 = guess_ab_col(x, "colistin"),
  GramNeg_4 = guess_ab_col(x, "cefotaxime"),
  GramNeg_5 = guess_ab_col(x, "ceftazidime"),
  GramNeg_6 = guess_ab_col(x, "meropenem"),
  warnings = TRUE,
  ...
)

doubles_equal(
  y,
  z,
  type = c("keyantibiotics", "points"),
  ignore_I = TRUE,
  points_threshold = 2,
  info = FALSE
)

Arguments

x  table with antibiotics coloms, like AMX or amox

col_mo  column name of the IDs of the microorganisms (see as.mo()), defaults to the
         first column of class mo. Values will be coerced using as.mo().

universal_1, universal_2, universal_3, universal_4, universal_5, universal_6
         column names of broad-spectrum antibiotics, case-insensitive. At default, the
         columns containing these antibiotics will be guessed with guess_ab_col().

GramPos_1, GramPos_2, GramPos_3, GramPos_4, GramPos_5, GramPos_6
         column names of antibiotics for Gram-positives, case-insensitive. At default, the
         columns containing these antibiotics will be guessed with guess_ab_col().
The function `key_antibiotics()` returns a character vector with 12 antibiotic results for every isolate. These isolates can then be compared using `key_antibiotics_equal()`, to check if two isolates have generally the same antibiogram. Missing and invalid values are replaced with a dot ("."), by `key_antibiotics()` and ignored by `key_antibiotics_equal()`.

The `first_isolate()` function only uses this function on the same microbial species from the same patient. Using this, e.g. an MRSA will be included after a susceptible S. aureus (MSSA) is found within the same patient episode. Without key antibiotic comparison it would not. See `first_isolate()` for more info.

At default, the antibiotics that are used for Gram-positive bacteria are:

- Amoxicillin
- Amoxicillin/clavulanic acid
- Cefuroxime
- Piperacillin/tazobactam
- Ciprofloxacin
- Trimethoprim/sulfamethoxazole
- Vancomycin
- Teicoplanin
- Tetracycline
- Erythromycin
- Oxacillin
- Rifampin

At default the antibiotics that are used for Gram-negative bacteria are:

- Amoxicillin
- Amoxicillin/clavulanic acid
- Cefuroxime
- Piperacillin/tazobactam
- Ciprofloxacin
- Trimethoprim/sulfamethoxazole
- Gentamicin
- Tobramycin
- Colistin
- Cefotaxime
- Ceftazidime
- Meropenem

The function `key_antibiotics_equal()` checks the characters returned by `key_antibiotics()` for equality, and returns a logical vector.

**Stable lifecycle**

The lifecycle of this function is **stable**. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

**Key antibiotics**

There are two ways to determine whether isolates can be included as first weighted isolates which will give generally the same results:

1. Using type = "keyantibiotics" and parameter `ignore_I`
   Any difference from S to R (or vice versa) will (re)select an isolate as a first weighted isolate. With `ignore_I = FALSE`, also differences from I to SIR (or vice versa) will lead to this. This is a reliable method and 30-35 times faster than method 2. Read more about this in the `key_antibiotics()` function.

2. Using type = "points" and parameter `points_threshold`
   A difference from I to SIR (or vice versa) means 0.5 points, a difference from S to R (or vice versa) means 1 point. When the sum of points exceeds `points_threshold`, which default to 2, an isolate will be (re)selected as a first weighted isolate.

kurtosis

See Also

first_isolate()

Examples

# 'example_isolates' is a dataset available in the AMR package.
# See ?example_isolates.

# output of the 'key_antibiotics' function could be like this:
strainA <- "SSSS.R.S..S"
strainB <- "SSSRSSRSSS"

# can those strings can be compared with:
key_antibiotics_equal(strainA, strainB)
# TRUE, because I is ignored (as well as missing values)

key_antibiotics_equal(strainA, strainB, ignore_I = FALSE)
# FALSE, because I is not ignored and so the 4th value differs

if (require("dplyr")) {
  # set key antibiotics to a new variable
  my_patients <- example_isolates %>%
    mutate(keyab = key_antibiotics(.)) %>%
    mutate(
      # now calculate first isolates
      first_regular = first_isolate(., col_keyantibiotics = FALSE),
      # and first WEIGHTED isolates
      first_weighted = first_isolate(., col_keyantibiotics = "keyab")
    )

  # Check the difference, in this data set it results in 7% more isolates:
  sum(my_patients$first_regular, na.rm = TRUE)
  sum(my_patients$first_weighted, na.rm = TRUE)
}

---

kurtosis  | Kurtosis of the sample

Description

Kurtosis is a measure of the "tailedness" of the probability distribution of a real-valued random variable. A normal distribution has a kurtosis of 3 and a excess kurtosis of 0.

Usage

kurtosis(x, na.rm = FALSE, excess = FALSE)
## Default S3 method:
`kurtosis(x, na.rm = FALSE, excess = FALSE)`

## S3 method for class 'matrix'
`kurtosis(x, na.rm = FALSE, excess = FALSE)`

## S3 method for class 'data.frame'
`kurtosis(x, na.rm = FALSE, excess = FALSE)`

### Arguments

- **x**: a vector of values, a matrix or a data frame
- **na.rm**: a logical to indicate whether NA values should be stripped before the computation proceeds
- **excess**: a logical to indicate whether the excess kurtosis should be returned, defined as the kurtosis minus 3.

### Stable lifecycle

The *lifecycle* of this function is **stable**. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

---

### Description

Functions in this **AMR** package are categorised using the lifecycle circle of the Tidyverse as found on [www.tidyverse.org/lifecycle](http://www.tidyverse.org/lifecycle).

This page contains a section for every lifecycle (with text borrowed from the aforementioned Tidyverse website), so they can be used in the manual pages of the functions.
Experimental lifecycle

The lifecycle of this function is **experimental**. An experimental function is in early stages of development. The unlying code might be changing frequently. Experimental functions might be removed without deprecation, so you are generally best off waiting until a function is more mature before you use it in production code. Experimental functions are only available in development versions of this AMR package and will thus not be included in releases that are submitted to CRAN, since such functions have not yet matured enough.

Maturing lifecycle

The lifecycle of this function is **maturing**. The unlying code of a maturing function has been roughed out, but finer details might still change. Since this function needs wider usage and more extensive testing, you are very welcome to suggest changes at our repository or write us an email (see section ‘Contact Us’).

Stable lifecycle

The lifecycle of this function is **stable**. In a stable function, major changes are unlikely. This means that the unlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the unlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

Retired lifecycle

The lifecycle of this function is **retired**. A retired function is no longer under active development, and (if appropriate) a better alternative is available. No new arguments will be added, and only the most critical bugs will be fixed. In a future version, this function will be removed.

Questioning lifecycle

The lifecycle of this function is **questioning**. This function might be no longer be optimal approach, or is it questionable whether this function should be in this AMR package at all.

like  

**Pattern Matching**

Description

Convenient wrapper around `grep()` to match a pattern: `x %like% pattern`. It always returns a logical vector and is always case-insensitive (use `x %like_case% pattern` for case-sensitive matching). Also, `pattern` can be as long as `x` to compare items of each index in both vectors, or they both can have the same length to iterate over all cases.
Usage

like(x, pattern, ignore.case = TRUE)

x %like% pattern

x %like_case% pattern

Arguments

x a character vector where matches are sought, or an object which can be coerced by as.character() to a character vector.

pattern a character string containing a regular expression (or character string for fixed = TRUE) to be matched in the given character vector. Coerced by as.character() to a character string if possible. If a character vector of length 2 or more is supplied, the first element is used with a warning.

ignore.case if FALSE, the pattern matching is case sensitive and if TRUE, case is ignored during matching.

Details

The %like% function:

- Is case-insensitive (use %like_case% for case-sensitive matching)
- Supports multiple patterns
- Checks if pattern is a regular expression and sets fixed = TRUE if not, to greatly improve speed
- Tries again with perl = TRUE if regex fails

Using RStudio? This function can also be inserted from the Addins menu and can have its own Keyboard Shortcut like Ctrl+Shift+L or Cmd+Shift+L (see Tools > Modify Keyboard Shortcuts...).

Value

A logical vector

Stable lifecycle

The lifecycle of this function is stable. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

grep()

Examples

```r
# simple test
a <- "This is a test"
b <- "TEST"
a %like% b
#> TRUE
b %like% a
#> FALSE

# also supports multiple patterns, length must be equal to n
a <- c("Test case", "Something different", "Yet another thing")
b <- c("case", "diff", "yet")
a %like% b
#> TRUE TRUE TRUE

# get isolates whose name start with 'Ent' or 'ent'
if (require("dplyr")) {
  example_isolates %>%
    filter(mo_name(mo) %like% "^ent")
}
```

---

**mdro**

*Determine multidrug-resistant organisms (MDRO)*

**Description**

Determine which isolates are multidrug-resistant organisms (MDRO) according to international and national guidelines.
Usage

mdro(
  x,
  guideline = "CMI2012",
  col_mo = NULL,
  info = interactive(),
  pct_required_classes = 0.5,
  combine_SI = TRUE,
  verbose = FALSE,
  ...
)

brmo(x, guideline = "BRMO", ...)

mrgn(x, guideline = "MRGN", ...)

mdr_tb(x, guideline = "TB", ...)

mdr_cmi2012(x, guideline = "CMI2012", ...)

eucast_exceptional_phenotypes(x, guideline = "EUCAST", ...)

Arguments

x data with antibiotic columns, such as amox, AMX and AMC

guideline a specific guideline to follow. When left empty, the publication by Magiorakos et al. (2012, Clinical Microbiology and Infection) will be followed, please see Details.

col_mo column name of the IDs of the microorganisms (see as.mo()), defaults to the first column of class mo. Values will be coerced using as.mo().

info a logical to indicate whether progress should be printed to the console, defaults to only print while in interactive sessions

pct_required_classes minimal required percentage of antimicrobial classes that must be available per isolate, rounded down. For example, with the default guideline, 17 antimicrobial classes must be available for S. aureus. Setting this pct_required_classes argument to 0.5 (default) means that for every S. aureus isolate at least 8 different classes must be available. Any lower number of available classes will return NA for that isolate.

combine_SI a logical to indicate whether all values of S and I must be merged into one, so resistance is only considered when isolates are R, not I. As this is the default behaviour of the mdro() function, it follows the redefinition by EUCAST about the interpretation of I (increased exposure) in 2019, see section 'Interpretation of S, I and R' below. When using combine_SI = FALSE, resistance is considered when isolates are R or I.

verbose a logical to turn Verbose mode on and off (default is off). In Verbose mode, the function does not return the MDRO results, but instead returns a data set
in logbook form with extensive info about which isolates would be MDRO-positive, or why they are not.

... column name of an antibiotic, please see section Antibiotics below

Details

For the pct_required_classes argument, values above 1 will be divided by 100. This is to support both fractions (0.75 or 3/4) and percentages (75).

Currently supported guidelines are (case-insensitive):

- guideline = "CMI2012"

- guideline = "EUCAST3.2" (or simply guideline = "EUCAST")
  The European international guideline - EUCAST Expert Rules Version 3.2 "Intrinsic Resistance and Unusual Phenotypes" (link)

- guideline = "EUCAST3.1"
  The European international guideline - EUCAST Expert Rules Version 3.1 "Intrinsic Resistance and Exceptional Phenotypes Tables" (link)

- guideline = "TB"
  The international guideline for multi-drug resistant tuberculosis - World Health Organization "Companion handbook to the WHO guidelines for the programmatic management of drug-resistant tuberculosis" (link)

- guideline = "MRGN"

- guideline = "BRMO"
  The Dutch national guideline - Rijksinstituut voor Volksgezondheid en Milieu "WIP-richtlijn BRMO (Bijzonder Resistente Micro-Organismen) (ZKH)" (link)

Please suggest your own (country-specific) guidelines by letting us know: https://github.com/msberends/AMR/issues/new.

Note: Every test that involves the Enterobacteriaceae family, will internally be performed using its newly named order Enterobacterales, since the Enterobacteriaceae family has been taxonomically reclassified by Adeolu et al. in 2016. Before that, Enterobacteriaceae was the only family under the Enterobacterales (with an i) order. All species under the old Enterobacteriaceae family are still under the new Enterobacterales (without an i) order, but divided into multiple families. The way tests are performed now by this mdro() function makes sure that results from before 2016 and after 2016 are identical.

Value

- CMI 2012 paper - function mdr_cmi2012() or mdro():
  Ordered factor with levels Negative < Multi-drug-resistant (MDR) < Extensively drug-resistant (XDR) < Pandrug-resistant (PDR)
• TB guideline - function `mdr_tb()` or `mdro(..., guideline = "TB")`:
  Ordered `factor` with levels Negative < Mono-resistant < Poly-resistant < Multi-drug-resistant < Extensively drug-resistant

• German guideline - function `mrgn()` or `mdro(..., guideline = "MRGN")`:
  Ordered `factor` with levels Negative < 3MRGN < 4MRGN

• Everything else:
  Ordered `factor` with levels Negative < Positive, unconfirmed < Positive. The value "Positive, unconfirmed" means that, according to the guideline, it is not entirely sure if the isolate is multi-drug resistant and this should be confirmed with additional (e.g. molecular) tests

**Stable lifecycle**

The *lifecycle* of this function is stable. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

**Antibiotics**

To define antibiotics column names, leave as is to determine it automatically with `guess_ab_col()` or input a text (case-insensitive), or use `NULL` to skip a column (e.g. `TIC = NULL` to skip ticarcillin). Manually defined but non-existing columns will be skipped with a warning.

The following antibiotics are used for the functions `eucast.rules()` and `mdro()`. These are shown below in the format 'name (antimicrobial ID, ATC code)', sorted alphabetically:

Amikacin (`AMK`, J01GB06), amoxicillin (`AMX`, J01CA04), amoxicillin/clavulanic acid (`AMC`, J01CR02), ampicillin (`AMP`, J01CA01), ampicillin/sulbactam (`SAM`, J01CR01), avoparcin (`AVO`, no ATC code), azithromycin (`AZM`, J01FA10), azlocillin (`AZL`, J01CA09), aztreonam (`ATM`, J01DF01), bacampicillin (`BAM`, J01CA06), benzylpenicillin (`PEN`, J01CE01), cadazolid (`CDZ`, J01DD09), capreomycin (`CAP`, J01CA05), carbenicillin (`CRB`, J01CA03), carindacillin (`CRN`, J01CA05), cefacetrile (`CAC`, J01DB10), cefaclor (`CEC`, J01DC04), cefadroxil (`CFR`, J01DB05), cefaloridine (`CID`, J01DB04), cefdinir (`CDR`, J01DD15), cefditoren (`DIT`, J01DB16), cefepime (`FEP`, J01DE01), cefetamet (`CAT`, J01DD10), cefixime (`CFM`, J01DD08), cefmenoxime (`CMX`, J01DD05), cefmetazole (`CMZ`, J01DC09), cefodizime (`DIZ`, J01DD09), cefonicid (`CID`, J01DC06), cefoperazone (`CFP`, J01DD12), cefoperazone/sulbactam (`CSL`, J01DD62), ceforanide (`CND`, J01DC11), cefotaxime (`CTX`, J01DD01), cefotetan (`CTT`, J01DC05), cefotiam (`CTF`, J01DC07), cefoxitin (`FOX`, J01DC01), cefoxitin screening (`FOX1`, no ATC code), cefpodoxime (`CPD`, J01DD13), cefprozil (`CPR`, J01DC10), cefroxadine (`CRO`, J01DB11), cefsoladin (`CSF`, J01DD03), ceftriaxone (`CPT`, J01DI02), cefazidime (`CAZ`, J01DD02), cefazidime/clavulanic acid (`CCV`, J01DD52), ceftazol (J01DB12), ceftibuten (`CTB`, J01DD14), ceftizoxime (`CZX`, J01DD07), cefotibprole (`BPR`, J01DI01), cefotibprole medocaril (`CFM`, J01DI01), ceftolozane/enzyme inhibitor (`CEI`, J01DI54), ceftriaxone (`CRO`, J01DD04), cefuroxime (`CXM`, J01DC02), cepalexin (`LEX`, J01DB01), cephalothin (`CEP`, J01DB03), cephradin (`CDZ`, J01DB08), cephradin (`CED`, J01DB09), chloramphenicol (`CHL`, J01BA01), ciprofloxacin (`CIP`, J01MA02), clarithromycin (`CLR`, J01FA09),
clindamycin (CLI, J01FF01), colistin (COL, J01XB01), cycloserine (CYC, J04AB01), dalbavancin (DAL, J01XA04), daptomycin (DAP, J01XX09), dibekacin (DBK, J01GB09), dirithromycin (DIR, J01FA13), doripenem (DOR, J01DH04), doxycycline (DOX, J01AA02), enoxacin (ENX, J01MA04), epinephrine (EPH, J01CA07), eravacycline (ERV, J01AA13), etrapenem (ETP, J01DH03), erythromycin (ERY, J01FA01), ethambutol (ETH, J04AK02), fidaxomicin (FDX, no ATC code), fexofenadine (FLE, J01MA08), flucloxacinil (FLC, J01CF05), flur-thymycin (FLR1, J01FA14), fosomycin (FOS, J01XX01), fusidic acid (FUS, J01X001), gentamicin (GEN, J01MA15), gentamicin-high (GEH, no ATC code), grepafloxacin (GRX, J01MA11), hetacillin (HET, J01CA18), imipenem (IPM, J01DH51), isepamicin (ISE, J01GB11), isoniazid (INH, J04AC01), josamycin (JOS, J01FA07), kanamycin (KAN, J01GB04), latamoxef (LTM, J01DD06), levofl oxacin (LVX, J01MA12), lincomycin (LIN, J01FF02), linezolid (LNZ, J01XX08), lomefloxacin (LOM, J01MA07), loracarbef (LOR, J01DC08), mecinillin (Amdinocillin) (MEC, J01CA11), meropenem (MEM, J01DH02), meropenem/vaborbactam (MEV, J01DH52), metampicillin (MTP, J01CA14), metronidazole (MTZ, J01X001), mezlocillin (MEZ, J01CA10), midemecamin (MID, J01FA03), minocycline (MIN, J01AA08), miocamycin (MIC, J01FA11), moxifloxacin (MFX, J01MA14), nalidixic acid (NAL, J01MB02), neomycin (NEO, J01GB05), netilmicin (NET, J01GB07), nitrofurantoin (NIT, J01XE01), norfloxacin (NOR, J01MA06), norvancomycin (NVA, no ATC code), novobiocin (NOV, Q01XX95), ofloxacin (OFX, J01MA01), oleandomycin (OLE, J01FA05), omadacycline (OMC, no ATC code), oritavancin (ORI, J01XA05), oxacinil (OXA, J01CF04), pazufloxacin (PAZ, J01MA18), pefloxacin (PEF, J01MA03), phenoxy-methylpenicillin (PhM, J01CE02), piperacillin (PIP, J01CA12), picicillin/tazobactam (TZP, J01CR05), pirilmycin (PRL, no ATC code), pivampicillin (PVM, J01CA02), pivmecillinam (PM, J01CA08), polymyxin B (PLB, J01X001), pristinamycin (PRI, J01FG01), prulofloxacin (PRU, J01MA17), pyrazinamidine (PZA, J01FA01), quinupristin/dalfopristin (QDA, J01FG02), ramoplanin (RAM, no ATC code), ribostamycin (RST, J01GB10), rifabutin (RIB, J04AB04), rifamicin (RIF, J04AB02), rifapentirine (RFP, J04AB05), rotigamicin (ROG, J01FA12), roxithromycin (ROX, J01FA06), rufofloxacin (RFL, J01MA10), sisomicin (SIS, J01GB08), sparfloxacin (SPX, J01MA09), spectino- mycin (SPT, J01XX01), spiramycin (SPI, J01FA02), streptoducin (STR, J01GA02), streptomyacin (STR1, J01GA01), streptomycin-high (STH, no ATC code), sulbenicillin (SBC, J01CA16), sulfadiazine (SDI, J01EC02), sulfadiazine/trimethoprim (SLT1, J01EE02), sulfadimethoxine (SUD, J01ED01), sulfadimidine (SM, J01EB03), sulfadimidine/trimethoprim (SLT2, J01EE05), sulfadiflorazole (SLF, J01EB05), sulfalene (SLF2, J01ED02), sulfamethazine (SZO, J01ED09), sulfamethazine (SLF3, J01ED07), sulfamethoxazole (SMX, J01EC01), sulfamethoxypyrazidine (SLF5, J01ED05), sulfamethoxazole (SMX, J01EC01), sulfamethoxazole/trimethoprim (SLT5, J01EE04), sulfanilamide (SLF9, J01EB06), sulaperin (SLF10, J01ED06), sulfaphenazole (SLF11, J01ED08), sulfapyridine (SLF12, J01EB04), sulfathiazole (SUT, J01EB07), sulfathiazole (SUT, J01EB08), talampicillin (TAL, J01CA15), tedizolid (TZD, J01XX11), teicoplanin (TEC, J01XA02), teicoplanin/macromethod (TCM, no ATC code), telavancin (TLY, J01XA03), temafloxacin (TMX, J01MA05), temocillin (TEM, J01CA17), tetracycline (TCY, J01AA07), thiaca-zone (THA, no ATC code), ticarcillin (TIC, J01CA13), ticarcillin/clavulanic acid (TCC, J01CR03), tigecycline (TGC, J01AA12), tobramycin (TOB, J01GB01), trimethoprime (TMP, J01EA01), trimethoprime/sulfamethoxazole (SXT, J01EE01), troleandomycin (TRL, J01FA08), trovafloxacin (TVA, J01MA13), vancomycin (VAN, J01CA01)

**Interpretation of R and S/I**

In 2019, the European Committee on Antimicrobial Susceptibility Testing (EUCAST) has decided to change the definitions of susceptibility testing categories R and S/I as shown below (https:}
A microorganism is categorised as Resistant when there is a high likelihood of therapeutic failure even when there is increased exposure. Exposure is a function of how the mode of administration, dose, dosing interval, infusion time, as well as distribution and excretion of the antimicrobial agent will influence the infecting organism at the site of infection.

A microorganism is categorised as Susceptible, standard dosing regimen, when there is a high likelihood of therapeutic success using a standard dosing regimen of the agent.

A microorganism is categorised as Susceptible, Increased exposure when there is a high likelihood of therapeutic success because exposure to the agent is increased by adjusting the dosing regimen or by its concentration at the site of infection.

This AMR package honours this new insight. Use \texttt{susceptibility()} (equal to \texttt{proportion_SI()}) to determine antimicrobial susceptibility and \texttt{count_susceptible()} (equal to \texttt{count_SI()}) to count susceptible isolates.

Read more on our website!

On our website \url{https://msberends.github.io/AMR/} you can find a comprehensive tutorial about how to conduct AMR analysis, the complete documentation of all functions and an example analysis using WHONET data. As we would like to better understand the backgrounds and needs of our users, please participate in our survey!

Source

Please see Details for the list of publications used for this function.

Examples

```r
mdro(example_isolates, guideline = "EUCAST")
```

```r
if (require("dplyr")) {
  example_isolates %>%
  mdro() %>%
  table()
  example_isolates %>%
  mutate(EUCAST = eucast_exceptional_phenotypes(.),
         BRMO = brmo(.),
         MRGN = mrgn(.))
}
```
Description

A data set containing the microbial taxonomy of six kingdoms from the Catalogue of Life. MO codes can be looked up using as.mo().

Usage

microorganisms

Format

A data.frame with 67,151 observations and 16 variables:

- **mo**
  ID of microorganism as used by this package
- **fullname**
  Full name, like "Escherichia coli"
- **kingdom, phylum, class, order, family, genus, species, subspecies**
  Taxonomic rank of the microorganism
- **rank**
  Text of the taxonomic rank of the microorganism, like "species" or "genus"
- **ref**
  Author(s) and year of concerning scientific publication
- **species_id**
  ID of the species as used by the Catalogue of Life
- **source**
  Either "CoL", "DSMZ" (see Source) or "manually added"
- **prevalence**
  Prevalence of the microorganism, see as.mo()
- **snomed**
  SNOMED code of the microorganism. Use mo_snomed() to retrieve it quickly, see mo_property().

Details

Manually added were:

- 11 entries of *Streptococcus* (beta-haemolytic: groups A, B, C, D, F, G, H, K and unspecified; other: viridans, milleri)
- 2 entries of *Staphylococcus* (coagulase-negative (CoNS) and coagulase-positive (CoPS))
- 3 entries of *Trichomonas* (*Trichomonas vaginalis*, and its family and genus)
- 1 entry of *Candida* (*Candida krusei*), that is not (yet) in the Catalogue of Life
• 1 entry of *Blastocystis* (*Blastocystis hominis*), although it officially does not exist (Noel *et al.* 2005, PMID 15634993)

• 5 other 'undefined' entries (unknown, unknown Gram negatives, unknown Gram positives, unknown yeast and unknown fungus)

• 6 families under the Enterobacterales order, according to Adeolu *et al.* (2016, PMID 27620848), that are not (yet) in the Catalogue of Life

• 7,411 species from the DSMZ (Deutsche Sammlung von Mikroorganismen und Zellkulturen) since the DSMZ contain the latest taxonomic information based on recent publications

**Direct download:**

This data set is available as 'flat file' for use even without R - you can find the file here:

The file in R format (with preserved data structure) can be found here:

- https://github.com/msberends/AMR/raw/master/data/microorganisms.rda

**About the records from DSMZ (see source)**

Names of prokaryotes are defined as being validly published by the International Code of Nomenclature of Bacteria. Validly published are all names which are included in the Approved Lists of Bacterial Names and the names subsequently published in the International Journal of Systematic Bacteriology (IJSB) and, from January 2000, in the International Journal of Systematic and Evolutionary Microbiology (IJSEM) as original articles or in the validation lists. *(from https://www.dsmz.de/services/online-tools/prokaryotic-nomenclature-up-to-date)*

In February 2020, the DSMZ records were merged with the List of Prokaryotic names with Standing in Nomenclature (LPSN).

**Catalogue of Life**

This package contains the complete taxonomic tree of almost all microorganisms (~70,000 species) from the authoritative and comprehensive Catalogue of Life (http://www.catalogueoflife.org). The Catalogue of Life is the most comprehensive and authoritative global index of species currently available.

Click here for more information about the included taxa. Check which version of the Catalogue of Life was included in this package with *catalogue_of_life_version()*.

**Reference data publicly available**

All reference data sets (about microorganisms, antibiotics, R/SI interpretation, EUCAST rules, etc.) in this AMR package are publicly and freely available. We continually export our data sets to formats for use in R, SPSS, SAS, Stata and Excel. We also supply flat files that are machine-readable and suitable for input in any software program, such as laboratory information systems. Please find all download links on our website, which is automatically updated with every code change.

microorganisms.codes Data set with 5,583 common microorganism codes

Description

A data set containing commonly used codes for microorganisms, from laboratory systems and WHONET. Define your own with set_mo_source(). They will all be searched when using as.mo() and consequently all the mo_* functions.

Usage

microorganisms.codes

Format

A data.frame with 5,583 observations and 2 variables:

- code
  Commonly used code of a microorganism
- mo
  ID of the microorganism in the microorganisms data set
Reference data publicly available

All reference data sets (about microorganisms, antibiotics, R/SI interpretation, EUCAST rules, etc.) in this AMR package are publicly and freely available. `as.mo()` microorganisms

---

microorganisms.old  Data set with previously accepted taxonomic names

Description

A data set containing old (previously valid or accepted) taxonomic names according to the Catalogue of Life. This data set is used internally by `as.mo()`.

Usage

microorganisms.old

Format

A data.frame with 12,708 observations and 4 variables:

- `fullname`
  Old full taxonomic name of the microorganism
- `fullname_new`
  New full taxonomic name of the microorganism
Catalogue of Life

This package contains the complete taxonomic tree of almost all microorganisms (~70,000 species) from the authoritative and comprehensive Catalogue of Life (http://www.catalogueoflife.org). as.mo() mo_property() microorganisms
Calculate the matching score for microorganisms

Description
This helper function is used by as.mo() to determine the most probable match of taxonomic records, based on user input.

Usage
mo_matching_score(x, n)

Arguments
x
Any user input value(s)

n
A full taxonomic name, that exists in microorganisms$fullname

Matching score for microorganisms
With ambiguous user input in as.mo() and all the mo_* functions, the returned results are chosen based on their matching score using mo_matching_score(). This matching score m, is calculated as:

\[ m(x, n) = \frac{l_n - 0.5 \cdot \min \left\{ l_n \cdot \text{lev}(x, n) \right\}}{l_n \cdot p_n \cdot k_n} \]

where:
- x is the user input;
- n is a taxonomic name (genus, species, and subspecies);
- \( l_n \) is the length of n;
- \( \text{lev} \) is the Levenshtein distance function, which counts any insertion, deletion and substitution as 1 that is needed to change x into n;
- \( p_n \) is the human pathogenic prevalence group of n, as described below;
- \( k_n \) is the taxonomic kingdom of n, set as Bacteria = 1, Fungi = 2, Protozoa = 3, Archaea = 4, others = 5.

The grouping into human pathogenic prevalence (p) is based on experience from several microbiological laboratories in the Netherlands in conjunction with international reports on pathogen prevalence. **Group 1** (most prevalent microorganisms) consists of all microorganisms where the taxonomic class is Gammaproteobacteria or where the taxonomic genus is Enterococcus, Staphylococcus or Streptococcus. This group consequently contains all common Gram-negative bacteria, such as Pseudomonas and Legionella and all species within the order Enterobacterales. **Group 2** consists of all microorganisms where the taxonomic phylum is Proteobacteria, Firmicutes, Actinobacteria

All matches are sorted descending on their matching score and for all user input values, the top match will be returned. This will lead to the effect that e.g., "E. coli" will return the microbial ID of *Escherichia coli* \((m = 0.688\), a highly prevalent microorganism found in humans) and not *Entamoeba coli* \((m = 0.079\), a less prevalent microorganism in humans), although the latter would alphabetically come first.

**Examples**

```
as.mo("E. coli")
mo_uncertainties()

mo_matching_score(x = "E. coli",
                n = c("Escherichia coli", "Entamoeba coli"))
```

**mo_property**

*Get properties of a microorganism*

**Description**

Use these functions to return a specific property of a microorganism based on the latest accepted taxonomy. All input values will be evaluated internally with `as.mo()`, which makes it possible to use microbial abbreviations, codes and names as input. Please see Examples.

**Usage**

```
mo_name(x, language = get_locale(), ...)
mo_fullname(x, language = get_locale(), ...)
mo_shortname(x, language = get_locale(), ...)
mo_subspecies(x, language = get_locale(), ...)
mo_species(x, language = get_locale(), ...)
```
mo_genus(x, language = get_locale(), ...)  
mo_family(x, language = get_locale(), ...)  
mo_order(x, language = get_locale(), ...)  
mo_class(x, language = get_locale(), ...)  
mo_phylum(x, language = get_locale(), ...)  
mo_kingdom(x, language = get_locale(), ...)  
mo_domain(x, language = get_locale(), ...)  
mo_type(x, language = get_locale(), ...)  
mo_gramstain(x, language = get_locale(), ...)  
mo_snomed(x, language = get_locale(), ...)  
mo_ref(x, language = get_locale(), ...)  
mo_authors(x, language = get_locale(), ...)  
mo_year(x, language = get_locale(), ...)  
mo_rank(x, language = get_locale(), ...)  
mo_taxonomy(x, language = get_locale(), ...)  
mo_synonyms(x, language = get_locale(), ...)  
mo_info(x, language = get_locale(), ...)  
mo_url(x, open = FALSE, language = get_locale(), ...)  
mo_property(x, property = "fullname", language = get_locale(), ...)  

Arguments

x  any (vector of) text that can be coerced to a valid microorganism code with as.mo()
language  language of the returned text, defaults to system language (see get.locale()) and can be overwritten by setting the option AMR.locale, e.g. options(AMR.locale = "de"), see translate. Use language = NULL or language = "" to prevent translation.
...  other parameters passed on to as.mo(), such as 'allow_uncertain' and 'ignore_pattern'
open  browse the URL using utils::browseURL()
property one of the column names of the microorganisms data set or "shortname"

Details
All functions will return the most recently known taxonomic property according to the Catalogue of Life, except for \texttt{mo_ref()}, \texttt{mo_authors()} and \texttt{mo_year()}. Please refer to this example, knowing that \textit{Escherichia blattae} was renamed to \textit{Shimwellia blattae} in 2010:

- \texttt{mo_name("Escherichia blattae")} will return "Shimwellia blattae" (with a message about the renaming)
- \texttt{mo_ref("Escherichia blattae")} will return "Burgess et al.,1973" (with a message about the renaming)
- \texttt{mo_ref("Shimwellia blattae")} will return "Priest et al.,2010" (without a message)

The short name - \texttt{mo_shortname()} - almost always returns the first character of the genus and the full species, like "\textit{E. coli}". Exceptions are abbreviations of staphylococci (like "\textit{CoNS}", Coagulase-Negative Staphylococci) and beta-haemolytic streptococci (like "\textit{GBS}", Group B Streptococci). Please bear in mind that e.g. \textit{E. coli} could mean \textit{Escherichia coli} (kingdom of Bacteria) as well as \textit{Entamoeba coli} (kingdom of Protozoa). Returning to the full name will be done using \texttt{as.mo()} internally, giving priority to bacteria and human pathogens, i.e. "\textit{E. coli}" will be considered \textit{Escherichia coli}. In other words, \texttt{mo_fullname(mo_shortname("Entamoeba coli"))} returns "\textit{Escherichia coli}".

Since the top-level of the taxonomy is sometimes referred to as 'kingdom' and sometimes as 'domain', the functions \texttt{mo_kingdom()} and \texttt{mo_domain()} return the exact same results.

The Gram stain - \texttt{mo_gramstain()} - will be determined based on the taxonomic kingdom and phylum. According to Cavalier-Smith (2002, PMID 11837318), who defined subkingdoms Negibacteria and Posibacteria, only these phyla are Posibacteria: Actinobacteria, Chloroflexi, Firmicutes and Tenericutes. These bacteria are considered Gram-positive - all other bacteria are considered Gram-negative. Species outside the kingdom of Bacteria will return a value \texttt{NA}.

All output will be \texttt{translated} where possible.

The function \texttt{mo_url()} will return the direct URL to the online database entry, which also shows the scientific reference of the concerned species.

Value
- An integer in case of \texttt{mo_year()}
- A list in case of \texttt{mo_taxonomy()} and \texttt{mo_info()}
- A named character in case of \texttt{mo_url()}
- A double in case of \texttt{mo_snomed()}
- A character in all other cases

Stable lifecycle
The \textit{lifecycle} of this function is \textit{stable}. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.
If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

**Matching score for microorganisms**

With ambiguous user input in `as.mo()` and all the `mo_*` functions, the returned results are chosen based on their matching score using `mo_matching_score()`. This matching score $m$, is calculated as:

\[ m_{(x,n)} = \frac{l_n - 0.5 \cdot \min \{ l_n \cdot \text{lev}(x,n) \}}{l_n \cdot p_n \cdot k_n} \]

where:

- $x$ is the user input;
- $n$ is a taxonomic name (genus, species, and subspecies);
- $l_n$ is the length of $n$;
- lev is the Levenshtein distance function, which counts any insertion, deletion and substitution as 1 that is needed to change $x$ into $n$;
- $p_n$ is the human pathogenic prevalence group of $n$, as described below;
- $k_n$ is the taxonomic kingdom of $n$, set as Bacteria = 1, Fungi = 2, Protozoa = 3, Archaea = 4, others = 5.

The grouping into human pathogenic prevalence ($p$) is based on experience from several microbiological laboratories in the Netherlands in conjunction with international reports on pathogen prevalence. **Group 1** (most prevalent microorganisms) consists of all microorganisms where the taxonomic class is Gammaproteobacteria or where the taxonomic genus is *Enterococcus*, *Staphylococcus* or *Streptococcus*. This group consequently contains all common Gram-negative bacteria, such as *Pseudomonas* and *Legionella* and all species within the order Enterobacterales. **Group 2** consists of all microorganisms where the taxonomic phylum is Proteobacteria, Firmicutes, Actinobacteria or Sarcomastigophora, or where the taxonomic genus is *Absidia*, *Acremonium*, *Actinotignum*, *Alternaria*, *Anaerobalbacter*, *Apophysomyces*, *Arachnia*, *Aspergillus*, *Aureobacterium*, *Aureobasidium*, *Bacteroides*, *Basidiobolus*, *Beauveria*, *Blastocystis*, *Branhamella*, *Calymmatobacterium*, *Can dida*, *Canpocytophaga*, *Catabacter*, *Chaetomium*, *Chryseobacterium*, *Chrysonilia*, *Cladophialophora*, *Cladosporium*, *Conidiobolus*, *Cryptococcus*, *Curvularia*, *Exophiala*, *Exserohilum*, *Flavobacterium*, *Fonsecaea*, *Fusarium*, *Fusobacterium*, *Hendersonula*, *Hypomyces*, *Koserella*, *Lelliottia*, *Leptotrichia*, *Malassezia*, *Mortierella*, *Mucor*, *Mycocentrospora*, *Mycoplasma*, *Nectria*, *Ochroconis*, *Oidiodendron*, *Phoma*, *Piedraia*, *Pithomyces*, *Pity rosporum*, *Prevotella*, *Pseudallescheria*, *Rhizomucor*, *Rhizopus*, *Rhodotorula*, *Scolecosporidium*, *Scopulariopsis*, *Scytalidium*, *Sporobolomyces*, *Stachybotrys*, *Stomatococcus*, *Treponema*, *Trichoderma*, *Trichophyton*, *Trichosporon*, *Tritirachium* or *Ureaplasma*. **Group 3** consists of all other microorganisms.

All matches are sorted descending on their matching score and for all user input values, the top match will be returned. This will lead to the effect that e.g., "E. coli" will return the microbial ID of *Escherichia coli* ($m = 0.688$, a highly prevalent microorganism found in humans) and not *Entamoeba coli* ($m = 0.079$, a less prevalent microorganism in humans), although the latter would alphabetically come first.
Catalogue of Life

This package contains the complete taxonomic tree of almost all microorganisms (~70,000 species) from the authoritative and comprehensive Catalogue of Life (http://www.catalogueoflife.org). The Catalogue of Life is the most comprehensive and authoritative global index of species currently available.

Click here for more information about the included taxa. Check which version of the Catalogue of Life was included in this package with catalogue_of_life_version().

Source

Reference data publicly available

All reference data sets (about microorganisms, antibiotics, R/SI interpretation, EUCAST rules, etc.) in this AMR package are publicly and freely available. We continually export our data sets to formats for use in R, SPSS, SAS, Stata and Excel. We also supply flat files that are machine-readable and suitable for input in any software program, such as laboratory information systems. Please find all download links on our website, which is automatically updated with every code change.

Read more on our website!

On our website https://msberends.github.io/AMR/ you can find a comprehensive tutorial about how to conduct AMR analysis, the complete documentation of all functions and an example analysis using WHONET data. As we would like to better understand the backgrounds and needs of our users, please participate in our survey!

---

**mo_source**

*User-defined reference data set for microorganisms*

**Description**

These functions can be used to redefine your own reference to be used in `as.mo()` and consequently all `mo_*` functions like `mo_genus()` and `mo_gramstain()`.

This is the fastest way to have your organisation (or analysis) specific codes picked up and translated by this package.

**Usage**

set_mo_source(path)

get_mo_source()

**Arguments**

*path* location of your reference file, see Details. Can be "", NULL or FALSE to delete the reference file.
Details

The reference file can be a text file separated with commas (CSV) or tabs or pipes, an Excel file (either 'xls' or 'xlsx' format) or an R object file (extension '.rds'). To use an Excel file, you will need to have the `readxl` package installed.

`set_mo_source()` will check the file for validity: it must be a data.frame, must have a column named "mo" which contains values from `microorganisms$mo` and must have a reference column with your own defined values. If all tests pass, `set_mo_source()` will read the file into R and will ask to export it to "~/.mo_source.rds". The CRAN policy disallows packages to write to the file system, although 'exceptions may be allowed in interactive sessions if the package obtains confirmation from the user'. For this reason, this function only works in interactive sessions so that the user can specifically confirm and allow that this file will be created.

The created compressed data file "~/.mo_source.rds" will be used at default for MO determination (function `as.mo()` and consequently all mo_* functions like `mo_genus()` and `mo_gramstain()`). The location of the original file will be saved as an R option with `options(mo_source = path)`. Its timestamp will be saved with `options(mo_source_datetime = ...)`.

The function `get_mo_source()` will return the data set by reading "~/.mo_source.rds" with `readRDS()`. If the original file has changed (by checking the aforementioned options mo_source and mo_source_datetime), it will call `set_mo_source()` to update the data file automatically if used in an interactive session.

Reading an Excel file (.xlsx) with only one row has a size of 8-9 kB. The compressed file created with `set_mo_source()` will then have a size of 0.1 kB and can be read by `get_mo_source()` in only a couple of microseconds (millionths of a second).

How to setup

Imagine this data on a sheet of an Excel file (mo codes were looked up in the microorganisms data set). The first column contains the organisation specific codes, the second column contains an MO code from this package:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Organisation XYZ</td>
<td>mo</td>
</tr>
<tr>
<td>2</td>
<td>lab_mo_ecoli</td>
<td>B_ESCHR_COLI</td>
</tr>
<tr>
<td>3</td>
<td>lab_mo_kpneumoniae</td>
<td>B_KLBSL_PNMN</td>
</tr>
<tr>
<td>4</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

We save it as "home/me/ourcodes.xlsx". Now we have to set it as a source:

```
set_mo_source("home/me/ourcodes.xlsx")
#> NOTE: Created mo_source file '~/mo_source.rds' from 'home/me/ourcodes.xlsx'
#> (columns "Organisation XYZ" and "mo")
```

It has now created a file "~/mo_source.rds" with the contents of our Excel file. Only the first column with foreign values and the 'mo' column will be kept when creating the RDS file.

And now we can use it in our functions:
as.mo("lab_mo_ecoli")
#> [1] B_ESCHR_COLI

mo_genus("lab_mo_kpneumoniae")
#> [1] "Klebsiella"

# other input values still work too
as.mo(c("Escherichia coli", "E. coli", "lab_mo_ecoli"))
#> [1] B_ESCHR_COLI B_ESCHR_COLI B_ESCHR_COLI

If we edit the Excel file by, let's say, adding row 4 like this:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>Organisation XYZ</td>
<td>mo</td>
</tr>
<tr>
<td>lab_mo_ecoli</td>
<td>B_ESCHR_COLI</td>
</tr>
<tr>
<td>lab_mo_kpneumoniae</td>
<td>B_KLBSL_PNMN</td>
</tr>
<tr>
<td>lab_Staph_aureus</td>
<td>B_STPHY_AURS</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

...any new usage of an MO function in this package will update your data file:

as.mo("lab_mo_ecoli")
#> NOTE: Updated mo_source file '~/mo_source.rds' from 'home/me/ourcodes.xlsx'
#> (columns "Organisation XYZ" and "mo")
#> [1] B_ESCHR_COLI

mo_genus("lab_Staph_aureus")
#> [1] "Staphylococcus"

To delete the reference data file, just use "", NULL or FALSE as input for set_mo_source():

set_mo_source(NULL)
# Removed mo_source file '~/mo_source.rds'.

If the original Excel file is moved or deleted, the mo_source file will be removed upon the next use of as.mo(). If the mo_source file is manually deleted (i.e. without using set_mo_source()), the references to the mo_source file will be removed upon the next use of as.mo().

**Stable lifecycle**

The lifecycle of this function is **stable**. In a stable function, major changes are unlikely. This means that the unlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the unlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.
Read more on our website!

On our website https://msberends.github.io/AMR/ you can find a comprehensive tutorial about how to conduct AMR analysis, the complete documentation of all functions and an example analysis using WHONET data. ---

**pca**

*Principal Component Analysis (for AMR)*

**Description**

Performs a principal component analysis (PCA) based on a data set with automatic determination for afterwards plotting the groups and labels, and automatic filtering on only suitable (i.e. non-empty and numeric) variables.

**Usage**

```r
pca(  
  x,  
  ...,  
  retx = TRUE,  
  center = TRUE,  
  scale. = TRUE,  
  tol = NULL,  
  rank. = NULL  
)
```

**Arguments**

- `x` 
  a data.frame containing numeric columns
- `...` 
  columns of `x` to be selected for PCA, can be unquoted since it supports quasiquotation.
- `retx` 
  a logical value indicating whether the rotated variables should be returned.
- `center` 
  a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of `x` can be supplied. The value is passed to `scale`.
- `scale.` 
  a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is `FALSE` for consistency with S, but in general scaling is advisable. Alternately, a vector of length equal the number of columns of `x` can be supplied. The value is passed to `scale`.
- `tol` 
  a value indicating the magnitude below which components should be omitted. (Components are omitted if their standard deviations are less than or equal to `tol` times the standard deviation of the first component.) With the default null setting, no components are omitted (unless `rank.` is specified less than `min(dim(x))`). Other settings for `tol` could be `tol = 0` or `tol = sqrt(.Machine$double.eps)`, which would omit essentially constant components.
 optionally, a number specifying the maximal rank, i.e., maximal number of principal components to be used. Can be set as alternative or in addition to tol, useful notably when the desired rank is considerably smaller than the dimensions of the matrix.

**Details**

The `pca()` function takes a `data.frame` as input and performs the actual PCA with the R function `prcomp()`.

The result of the `pca()` function is a `prcomp` object, with an additional attribute `non_numeric_cols` which is a vector with the column names of all columns that do not contain numeric values. These are probably the groups and labels, and will be used by `ggplot_pca()`.

**Value**

An object of classes `pca` and `prcomp`

**Maturing lifecycle**

The lifecycle of this function is maturing. The underlying code of a maturing function has been roughed out, but finer details might still change. Since this function needs wider usage and more extensive testing, you are very welcome to suggest changes at our repository or write us an email (see section 'Contact Us').

**Examples**

```r
if (require("dplyr")) {
  # calculate the resistance per group first
  resistance_data <- example_isolates %>%
    group_by(order = mo_order(mo), genus = mo_genus(mo)) %>%
    summarise_if(is.rsi, resistance) # then get resistance of all drugs

  # now conduct PCA for certain antimicrobial agents
  pca_result <- resistance_data %>%
    pca(AMC, CXM, CTX, CAZ, GEN, TOB, TMP, SXT)

  pca_result
  summary(pca_result)
  biplot(pca_result)
  ggplot_pca(pca_result) # a new and convenient plot function
}
```

# `example_isolates` is a dataset available in the AMR package.
# See ?example_isolates.
Calculate microbial resistance

Description

These functions can be used to calculate the (co-)resistance or susceptibility of microbial isolates (i.e. percentage of S, SI, I, IR or R). All functions support quasiquotation with pipes, can be used in `summarise()` from the `dplyr` package and also support grouped variables, please see Examples. `resistance()` should be used to calculate resistance, `susceptibility()` should be used to calculate susceptibility.

Usage

```r
resistance(..., minimum = 30, as_percent = FALSE, only_all_tested = FALSE)

susceptibility(..., minimum = 30, as_percent = FALSE, only_all_tested = FALSE)

proportion_R(..., minimum = 30, as_percent = FALSE, only_all_tested = FALSE)

proportion_IR(..., minimum = 30, as_percent = FALSE, only_all_tested = FALSE)

proportion_I(..., minimum = 30, as_percent = FALSE, only_all_tested = FALSE)

proportion_SI(..., minimum = 30, as_percent = FALSE, only_all_tested = FALSE)

proportion_S(..., minimum = 30, as_percent = FALSE, only_all_tested = FALSE)

proportion_df(
  data,
  translate_ab = "name",
  language = get.locale(),
  minimum = 30,
  as_percent = FALSE,
  combine_SI = TRUE,
  combine_IR = FALSE
)

rsi_df(
  data,
  translate_ab = "name",
  language = get.locale(),
  minimum = 30,
  as_percent = FALSE,
  combine_SI = TRUE,
  combine_IR = FALSE
)
```
Arguments

... one or more vectors (or columns) with antibiotic interpretations. They will be transformed internally with as.rsi() if needed. Use multiple columns to calculate (the lack of) co-resistance: the probability where one of two drugs have a resistant or susceptible result. See Examples.

minimum the minimum allowed number of available (tested) isolates. Any isolate count lower than minimum will return NA with a warning. The default number of 30 isolates is advised by the Clinical and Laboratory Standards Institute (CLSI) as best practice, see Source.

as_percent a logical to indicate whether the output must be returned as a hundred fold with % sign (a character). A value of 0.123456 will then be returned as "12.3%".

only_all_tested (for combination therapies, i.e. using more than one variable for ...): a logical to indicate that isolates must be tested for all antibiotics, see section Combination therapy below

data a data.frame containing columns with class rsi (see as.rsi())

translate_ab a column name of the antibiotics data set to translate the antibiotic abbreviations to, using ab_property(). Use a value

language language of the returned text, defaults to system language (see get_locale()) and can also be set with getOption("AMR_locale"). Use language = NULL or language = "" to prevent translation.

combine_SI a logical to indicate whether all values of S and I must be merged into one, so the output only consists of S+I vs. R (susceptible vs. resistant). This used to be the parameter combine_IR, but this now follows the redefinition by EUCAST about the interpretation of I (increased exposure) in 2019, see section 'Interpretation of S, I and R' below. Default is TRUE.

combine_IR a logical to indicate whether all values of I and R must be merged into one, so the output only consists of S vs. I+R (susceptible vs. non-susceptible). This is outdated, see parameter combine_SI.

Details

The function resistance() is equal to the function proportion_R(). The function susceptibility() is equal to the function proportion_SI().

Remember that you should filter your table to let it contain only first isolates! This is needed to exclude duplicates and to reduce selection bias. Use first_isolate() to determine them in your data set.

These functions are not meant to count isolates, but to calculate the proportion of resistance/susceptibility. Use the count() functions to count isolates. The function susceptibility() is essentially equal to count_susceptible() / count_all(). Low counts can influence the outcome - the proportion functions may camouflage this, since they only return the proportion (albeit being dependent on the minimum parameter).

The function proportion_df() takes any variable from data that has an rsi class (created with as.rsi()) and calculates the proportions R, I and S. It also supports grouped variables. The function rsi_df() works exactly like proportion_df(), but adds the number of isolates.
**Value**

A double or, when as_percent = TRUE, a character.

**Combination therapy**

When using more than one variable for ... (= combination therapy), use only_all_tested to only count isolates that are tested for all antibiotics/variables that you test them for. See this example for two antibiotics, Drug A and Drug B, about how susceptibility() works to calculate the %SI:

<table>
<thead>
<tr>
<th>Drug A</th>
<th>Drug B</th>
<th>only_all_tested = FALSE</th>
<th>only_all_tested = TRUE</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>include as numerator</td>
<td>include as denominator</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>S or I</td>
<td>S or I</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>R</td>
<td>S or I</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>&lt;NA&gt;</td>
<td>S or I</td>
<td>X</td>
<td>-</td>
</tr>
<tr>
<td>S or I</td>
<td>R</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>R</td>
<td>R</td>
<td>-</td>
<td>X</td>
</tr>
<tr>
<td>&lt;NA&gt;</td>
<td>R</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>S or I</td>
<td>&lt;NA&gt;</td>
<td>X</td>
<td>-</td>
</tr>
<tr>
<td>R</td>
<td>&lt;NA&gt;</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>&lt;NA&gt;</td>
<td>&lt;NA&gt;</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

Please note that, in combination therapies, for only_all_tested = TRUE applies that:

\[
\text{count}_S() + \text{count}_I() + \text{count}_R() = \text{count}_\text{all}()
\]

\[
\text{proportion}_S() + \text{proportion}_I() + \text{proportion}_R() = 1
\]

and that, in combination therapies, for only_all_tested = FALSE applies that:

\[
\text{count}_S() + \text{count}_I() + \text{count}_R() \geq \text{count}_\text{all}()
\]

\[
\text{proportion}_S() + \text{proportion}_I() + \text{proportion}_R() \geq 1
\]

Using only_all_tested has no impact when only using one antibiotic as input.

**Stable lifecycle**

The lifecycle of this function is stable. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.
Interpretation of R and S/I

In 2019, the European Committee on Antimicrobial Susceptibility Testing (EUCAST) has decided to change the definitions of susceptibility testing categories R and S/I as shown below (https://www.eucast.org/newsandr/).

- **R = Resistant**
  A microorganism is categorised as **Resistant** when there is a high likelihood of therapeutic failure even when there is increased exposure. Exposure is a function of how the mode of administration, dose, dosing interval, infusion time, as well as distribution and excretion of the antimicrobial agent will influence the infecting organism at the site of infection.

- **S = Susceptible**
  A microorganism is categorised as **Susceptible, standard dosing regimen**, when there is a high likelihood of therapeutic success using a standard dosing regimen of the agent.

- **I = Increased exposure, but still susceptible**
  A microorganism is categorised as **Susceptible, Increased exposure** when there is a high likelihood of therapeutic success because exposure to the agent is increased by adjusting the dosing regimen or by its concentration at the site of infection.

This AMR package honours this new insight. Use `susceptibility()` (equal to `proportion_SI()`) to determine antimicrobial susceptibility and `count_susceptible()` (equal to `count_SI()`) to count susceptible isolates.

Read more on our website!

On our website [https://msberends.github.io/AMR/](https://msberends.github.io/AMR/) you can find a comprehensive tutorial about how to conduct AMR analysis, the complete documentation of all functions and an example analysis using WHONET data. - `count()` to count resistant and susceptible isolates.

Examples

```r
# example_isolates is a data set available in the AMR package.
?example_isolates

resistance(example_isolates$AMX)  # determines %R
susceptibility(example_isolates$AMX)  # determines %S+I

# be more specific
proportion_S(example_isolates$AMX)
proportion_SI(example_isolates$AMX)
```
proportion_I(example_isolates$AMX)
proportion_IR(example_isolates$AMX)
proportion_R(example_isolates$AMX)

if (require("dplyr")) {
  example_isolates %>%
  group_by(hospital_id) %>%
  summarise(r = resistance(CIP),
             n = n_rsi(CIP)) # n_rsi works like n_distinct in dplyr, see ?n_rsi

  example_isolates %>%
  group_by(hospital_id) %>%
  summarise(R = resistance(CIP, as_percent = TRUE),
             SI = susceptibility(CIP, as_percent = TRUE),
             n1 = count_all(CIP), # the actual total; sum of all three
             n2 = n_rsi(CIP), # same - analogous to n_distinct
             total = n()) # NOT the number of tested isolates!

# Calculate co-resistance between amoxicillin/clav acid and gentamicin,
# so we can see that combination therapy does a lot more than mono therapy:
example_isolates %>% susceptibility(AMC) # %SI = 76.3%
example_isolates %>% count_all(AMC) # n = 1879

example_isolates %>% susceptibility(GEN) # %SI = 75.4%
example_isolates %>% count_all(GEN) # n = 1855

example_isolates %>% susceptibility(AMC, GEN) # %SI = 94.1%
example_isolates %>% count_all(AMC, GEN) # n = 1939

# See Details on how 'only_all_tested' works. Example:
example_isolates %>%
  summarise(numerator = count_susceptible(AMC, GEN),
             denominator = count_all(AMC, GEN),
             proportion = susceptibility(AMC, GEN))

example_isolates %>%
  summarise(numerator = count_susceptible(AMC, GEN, only_all_tested = TRUE),
             denominator = count_all(AMC, GEN, only_all_tested = TRUE),
             proportion = susceptibility(AMC, GEN, only_all_tested = TRUE))

example_isolates %>%
  group_by(hospital_id) %>%
  summarise(cipro_p = susceptibility(CIP, as_percent = TRUE),
             cipro_n = count_all(CIP),
             genta_p = susceptibility(GEN, as_percent = TRUE),
             genta_n = count_all(GEN),
             combination_p = susceptibility(CIP, GEN, as_percent = TRUE),
             combination_n = count_all(CIP, GEN))

# Get proportions S/I/R immediately of all rsi columns
example_isolates %>%
```r
select(AMX, CIP) %>%
proportion_df(translate = FALSE)

# It also supports grouping variables
example_isolates %>%
select(hospital_id, AMX, CIP) %>%
group_by(hospital_id) %>%
proportion_df(translate = FALSE)
```

---

**p_symbol**

*Symbol of a p-value*

**Description**

Return the symbol related to the p-value: `0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1`. Values above `p = 1` will return \textbf{NA}.

**Usage**

```r
p_symbol(p, emptychar = " ")
```

**Arguments**

- `p`  
  p value

- `emptychar`  
  text to show when `p > 0.1`

**Details**

\textbf{NOTE}: this function will be moved to the cleaner package when a new version is being published on CRAN.

**Value**

Text

**Questioning lifecycle**

The lifecycle of this function is questioning. This function might be no longer be optimal approach, or is it questionable whether this function should be in this AMR package at all.

**Read more on our website!**

On our website [https://msberends.github.io/AMR/](https://msberends.github.io/AMR/) you can find a comprehensive tutorial about how to conduct AMR analysis, the complete documentation of all functions and an example analysis using WHONET data. As we would like to better understand the backgrounds and needs of our users, please participate in our survey!
resistance_predict | Predict antimicrobial resistance

Description

Create a prediction model to predict antimicrobial resistance for the next years on statistical solid ground. Standard errors (SE) will be returned as columns se_min and se_max. See Examples for a real live example.

Usage

resistance_predict(
  x,
  col_ab,
  col_date = NULL,
  year_min = NULL,
  year_max = NULL,
  year_every = 1,
  minimum = 30,
  model = NULL,
  I_as_S = TRUE,
  preserve_measurements = TRUE,
  info = interactive(),
  ...
)

rsi_predict(
  x,
  col_ab,
  col_date = NULL,
  year_min = NULL,
  year_max = NULL,
  year_every = 1,
  minimum = 30,
  model = NULL,
  I_as_S = TRUE,
  preserve_measurements = TRUE,
  info = interactive(),
  ...
)

## S3 method for class 'resistance_predict'
plot(x, main = paste("Resistance Prediction of", x_name), ...)

ggplot_rsi_predict(
  x,
  main = paste("Resistance Prediction of", x_name),
  ...
resistance_predict

ribbon = TRUE,

Arguments

x
  a data.frame containing isolates.
col_ab
  column name of x containing antimicrobial interpretations ("R", "I" and "S")
col_date
  column name of the date, will be used to calculate years if this column doesn’t consist of years already, defaults to the first column of with a date class
year_min
  lowest year to use in the prediction model, defaults to the lowest year in col_date
year_max
  highest year to use in the prediction model, defaults to 10 years after today
year_every
  unit of sequence between lowest year found in the data and year_max
minimum
  minimal amount of available isolates per year to include. Years containing less observations will be estimated by the model.
model
  the statistical model of choice. This could be a generalised linear regression model with binomial distribution (i.e. using ‘glm(..., family = binomial)’, assuming that a period of zero resistance was followed by a period of increasing resistance leading slowly to more and more resistance. See Details for all valid options.
I_as_S
  a logical to indicate whether values I should be treated as S (will otherwise be treated as R). The default, TRUE, follows the redefinition by EUCAST about the interpretation of I (increased exposure) in 2019, see section Interpretation of S, I and R below.
preserve_measurements
  a logical to indicate whether predictions of years that are actually available in the data should be overwritten by the original data. The standard errors of those years will be NA.
info
  a logical to indicate whether textual analysis should be printed with the name and summary() of the statistical model.
...  
  parameters passed on to functions
main
  title of the plot
ribbon
  a logical to indicate whether a ribbon should be shown (default) or error bars

Details

Valid options for the statistical model (parameter model) are:

- "binomial" or "binom" or "logit": a generalised linear regression model with binomial distribution
- "loglin" or "poisson": a generalised log-linear regression model with poisson distribution
- "lin" or "linear": a linear regression model
Value

A data.frame with extra class resistance_predict with columns:

- year
- value, the same as estimated when preserve_measurements = FALSE, and a combination of observed and estimated otherwise
- se_min, the lower bound of the standard error with a minimum of 0 (so the standard error will never go below 0%)
- se_max the upper bound of the standard error with a maximum of 1 (so the standard error will never go above 100%)
- observations, the total number of available observations in that year, i.e. $S + I + R$
- observed, the original observed resistant percentages
- estimated, the estimated resistant percentages, calculated by the model

Furthermore, the model itself is available as an attribute: attributes(x)$model, please see Examples.

Maturing lifecycle

The lifecycle of this function is maturing. The underlying code of a maturing function has been roughed out, but finer details might still change. Since this function needs wider usage and more extensive testing, you are very welcome to suggest changes at our repository or write us an email (see section 'Contact Us').

Interpretation of R and S/I

In 2019, the European Committee on Antimicrobial Susceptibility Testing (EUCAST) has decided to change the definitions of susceptibility testing categories R and S/I as shown below (https://www.eucast.org/news/andr/).

- **R = Resistant**
  A microorganism is categorised as Resistant when there is a high likelihood of therapeutic failure even when there is increased exposure. Exposure is a function of how the mode of administration, dose, dosing interval, infusion time, as well as distribution and excretion of the antimicrobial agent will influence the infecting organism at the site of infection.

- **S = Susceptible**
  A microorganism is categorised as Susceptible, standard dosing regimen, when there is a high likelihood of therapeutic success using a standard dosing regimen of the agent.

- **I = Increased exposure, but still susceptible**
  A microorganism is categorised as Susceptible, Increased exposure when there is a high likelihood of therapeutic success because exposure to the agent is increased by adjusting the dosing regimen or by its concentration at the site of infection.

This AMR package honours this new insight. Use susceptibility() (equal to proportion_SI()) to determine antimicrobial susceptibility and count_susceptible() (equal to count_SI()) to count susceptible isolates.

The `proportion()` functions to calculate resistance

Models: `lm()` `glm()`

Examples

```r
x <- resistance_predict(example_isolates, 
  col_ab = "AMX", 
  year_min = 2010, 
  model = "binomial")

plot(x)
if (require("ggplot2")) {
  ggplot_rsi_predict(x)
}

# using dplyr:
if (require("dplyr")) {
  x <- example_isolates %>%
    filter_first_isolate() %>%
    filter(mo_genus(mo) == "Staphylococcus") %>%
    resistance_predict("PEN", model = "binomial")
  plot(x)

  # get the model from the object
  mymodel <- attributes(x)$model
  summary(mymodel)
}

# create nice plots with ggplot2 yourself
if (require("dplyr") & require("ggplot2")) {
  data <- example_isolates %>%
    filter(mo == as.mo("E. coli")) %>%
    resistance_predict(col_ab = "AMX", 
      col_date = "date", 
      model = "binomial", 
      info = FALSE, 
      minimum = 15)

  ggplot(data, 
    aes(x = year)) +
  geom_col(aes(y = value), 
    fill = "grey75") +
  geom_errorbar(aes(ymin = se_min, 
```
Data set for R/SI interpretation

Description
Data set to interpret MIC and disk diffusion to R/SI values. Included guidelines are CLSI (2010-2019) and EUCAST (2011-2020). Use `as.rsi()` to transform MICs or disks measurements to R/SI values.

Usage

`rsi_translation`

Format
A data.frame with 18,650 observations and 10 variables:

- **guideline**
  Name of the guideline
- **method**
  Either "MIC" or "DISK"
- **site**
  Body site, e.g. "Oral" or "Respiratory"
- **mo**
  Microbial ID, see `as.mo()`
- **ab**
  Antibiotic ID, see `as.ab()`
- **ref_tbl**
  Info about where the guideline rule can be found
- **disk_dose**
  Dose of the used disk diffusion method
- **breakpoint_S**
  Lowest MIC value or highest number of millimetres that leads to "S"
• breakpoint_R
  Highest MIC value or lowest number of millimetres that leads to "R"

• uti
  A logical value (TRUE/FALSE) to indicate whether the rule applies to a urinary tract infection (UTI)

Details

The repository of this AMR package contains a file comprising this exact data set: https://github.com/msberends/AMR/blob/master/data-raw/rsi_translation.txt. This file allows for machine reading EUCAST and CLSI guidelines, which is almost impossible with the Excel and PDF files distributed by EUCAST and CLSI. The file is updated automatically.

Reference data publicly available

All reference data sets (about microorganisms, antibiotics, R/SI interpretation, EUCAST rules, etc.) in this AMR package are publicly and freely available. We continually export our data sets to formats for use in R, SPSS, SAS, Stata and Excel. We also supply flat files that are machine-readable and suitable for input in any software program, such as laboratory information systems. Please find all download links on our website, which is automatically updated with every code change.

Read more on our website!

On our website https://msberends.github.io/AMR/ you can find a comprehensive tutorial about how to conduct AMR analysis, the complete documentation of all functions and an example analysis using WHONET data. As we would like to better understand the backgrounds and needs of our users, please participate in our survey!

intrinsic_resistant

---

<table>
<thead>
<tr>
<th>skwness</th>
<th>Skewness of the sample</th>
</tr>
</thead>
</table>

Description

Skewness is a measure of the asymmetry of the probability distribution of a real-valued random variable about its mean.

When negative ('left-skewed'): the left tail is longer; the mass of the distribution is concentrated on the right of a histogram. When positive ('right-skewed'): the right tail is longer; the mass of the distribution is concentrated on the left of a histogram. A normal distribution has a skewness of 0.
Usage

```r
skewness(x, na.rm = FALSE)
```

```r
## Default S3 method:
skewness(x, na.rm = FALSE)
```

```r
## S3 method for class 'matrix'
skewness(x, na.rm = FALSE)
```

```r
## S3 method for class 'data.frame'
skewness(x, na.rm = FALSE)
```

Arguments

- `x` a vector of values, a `matrix` or a `data.frame`
- `na.rm` a logical value indicating whether NA values should be stripped before the computation proceeds

Stable lifecycle

The lifecycle of this function is stable. In a stable function, major changes are unlikely. This means that the underlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the underlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit a message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

---

translate Translate strings from AMR package

Description

For language-dependent output of AMR functions, like `mo_name()`, `mo_gramstain()`, `mo_type()` and `ab_name()`.
Usage

get_locale()

Details

Strings will be translated to foreign languages if they are defined in a local translation file. Additions to this file can be suggested at our repository. The file can be found here: https://github.com/msberends/AMR/blob/master/data-raw/translations.tsv. This file will be read by all functions where a translated output can be desired, like all mo_property() functions (mo_name(), mo_gramstain(), mo_type(), etc.) and ab_property() functions (ab_name(), ab_group() etc.).

Currently supported languages are: Dutch, English, French, German, Italian, Portuguese, Spanish. Please note that currently not all these languages have translations available for all antimicrobial agents and colloquial microorganism names.

Please suggest your own translations by creating a new issue on our repository.

Changing the default language:

The system language will be used at default (as returned by Sys.getenv("LANG") or, if LANG is not set, Sys.getlocale()), if that language is supported. But the language to be used can be overwritten in two ways and will be checked in this order:

1. Setting the R option AMR_locale, e.g. by running options(AMR_locale = "de")
2. Setting the system variable LANGUAGE or LANG, e.g. by adding LANGUAGE="de_DE.utf8" to your .Renviron file in your home directory

So if the R option AMR_locale is set, the system variables LANGUAGE and LANG will be ignored.

Stable lifecycle

The lifecycle of this function is stable. In a stable function, major changes are unlikely. This means that the unlying code will generally evolve by adding new arguments; removing arguments or changing the meaning of existing arguments will be avoided.

If the unlying code needs breaking changes, they will occur gradually. For example, a parameter will be deprecated and first continue to work, but will emit an message informing you of the change. Next, typically after at least one newly released version on CRAN, the message will be transformed to an error.

As we would like to better understand the backgrounds and needs of our users, please participate in our survey!

Examples

# The 'language' parameter of below functions
# will be set automatically to your system language
# with get_locale()

# English
WHOCC

Description

All antimicrobial drugs and their official names, ATC codes, ATC groups and defined daily dose (DDD) are included in this package, using the WHO Collaborating Centre for Drug Statistics Methodology.

WHOCC

These have become the gold standard for international drug utilisation monitoring and research.

The WHOCC is located in Oslo at the Norwegian Institute of Public Health and funded by the Norwegian government. The European Commission is the executive of the European Union and promotes its general interest.

NOTE: The WHOCC copyright does not allow use for commercial purposes, unlike any other info from this package. See https://www.whocc.no/copyright_disclaimer/.

WHONET

Data set with 500 isolates - WHONET example

Description

This example data set has the exact same structure as an export file from WHONET. Such files can be used with this package, as this example data set shows. The antibiotic results are from our example_isolates data set. All patient names are created using online surname generators and are only in place for practice purposes.

Usage

WHONET

Format

A data.frame with 500 observations and 53 variables:

- Identification number
  ID of the sample
- Specimen number
  ID of the specimen
- Organism
  Name of the microorganism. Before analysis, you should transform this to a valid microbial class, using as.mo().
- Country
  Country of origin
- Laboratory
  Name of laboratory
- Last name
  Fictitious last name of patient
- First name
  Fictitious initial of patient
• Sex
  Fictitious gender of patient
• Age
  Fictitious age of patient
• Age category
  Age group, can also be looked up using `age_groups()`
• Date of admission
  Date of hospital admission
• Specimen date
  Date when specimen was received at laboratory
• Specimen type
  Specimen type or group
• Specimen type (Numeric)
  Translation of "Specimen type"
• Reason
  Reason of request with Differential Diagnosis
• Isolate number
  ID of isolate
• Organism type
  Type of microorganism, can also be looked up using `mo_type()`
• Serotype
  Serotype of microorganism
• Beta-lactamase
  Microorganism produces beta-lactamase?
• ESBL
  Microorganism produces extended spectrum beta-lactamase?
• Carbapenemase
  Microorganism produces carbapenemase?
• MRSA screening test
  Microorganism is possible MRSA?
• Inducible clindamycin resistance
  Clindamycin can be induced?
• Comment
  Other comments
• Date of data entry
  Date this data was entered in WHONET
• `AMP_ND10:CIP_EE`
  28 different antibiotics. You can lookup the abbreviations in the `antibiotics` data set, or use e.g. `ab_name("AMP")` to get the official name immediately. Before analysis, you should transform this to a valid antibiotic class, using `as.rsi()`.
