# Package 'CBPS'

October 12, 2022

Version 0.23

Date 2022-01-18

Title Covariate Balancing Propensity Score

**Depends** R (>= 3.4), MASS, MatchIt, nnet, numDeriv, glmnet

## **Imports**

Description Implements the covariate balancing propensity score (CBPS) proposed by Imai and Ratkovic (2014) < DOI:10.1111/rssb.12027>. The propensity score is estimated such that it maximizes the resulting covariate balance as well as the prediction of treatment assignment. The method, therefore, avoids an iteration between model fitting and balance checking. The package also implements optimal CBPS from Fan et al. (in-press) <DOI:10.1080/07350015.2021.2002159>, several extensions of the CBPS beyond the cross-sectional, binary treatment setting. They include the CBPS for longitudinal settings so that it can be used in conjunction with marginal structural models from Imai and Ratkovic (2015) <DOI:10.1080/01621459.2014.956872>, treatments with three- and four-valued treatment variables, continuous-valued treatments from Fong, Hazlett, and Imai (2018) <DOI:10.1214/17-AOAS1101>, propensity score estimation with a large number of covariates from Ning, Peng, and Imai (2020) < DOI:10.1093/biomet/asaa020 >, and the situation with multiple distinct binary treatments administered simultaneously. In the future it will be extended to other settings including the generalization of experimental and instrumental variable estimates.

AsyV	ar Asymptotic Variance and Confidence Interval Estimation of the ATE	

# Description

AsyVar estimates the asymptotic variance of the ATE obtained with the CBPS or oCBPS method. It also returns the finite variance estimate, the finite standard error, and a CI for the ATE.

AsyVar 3

### Usage

```
AsyVar(
Y,
Y_1_hat = NULL,
Y_0_hat = NULL,
CBPS_obj,
method = "CBPS",
X = NULL,
TL = NULL,
pi = NULL,
mu = NULL,
CI = 0.95
)
```

## Arguments

Y The vector of actual outcome values (observations).

Y\_1\_hat The vector of estimated outcomes according to the treatment model. (AsyVar automatically sets the treatment model as a linear regression model and it is fitted within the function.) If CBPS\_obj is specified, or if X and TL are specified,

this is unnecessary.

Y\_0\_hat The vector of estimated outcomes according to the control model. (AsyVar au-

tomatically sets the control model as a linear regression model and it is fitted within the function.) If CBPS\_obj is specified, or if X and TL are specified, this

is unnecessary.

CBPS\_obj An object obtained with the CBPS function. If this object is not sepecified, then

X, TL, pi, and mu must all be specified instead.

method The specific method to be considered. Either "CBPS" or "oCBPS" must be se-

lected.

X The matrix of covariates with the rows corresponding to the observations and the columns corresponding to the variables. The left most column must be a

column of 1's for the intercept. (X is not necessary if CBPS\_obj is specified.)

TL The vector of treatment labels. More specifically, the label is 1 if it is in the treatment group and 0 if it is in the control group. (TL is not necessary if CBPS\_obj

is specified.)

pi The vector of estimated propensity scores. (pi is not necessary if CBPS\_obj is

specified.)

mu The estimated average treatment effect obtained with either the CBPS or oCBPS

method. (mu is not necessary if CBPS\_obj is specified.)

CI The specified confidence level (between 0 and 1) for calculating the confidence

interval for the average treatment effect. Default value is 0.95.

#### Value

mu. hat The estimated average treatment effect,  $hat\mu$ .

4 AsyVar

asy.var	The estimated asymptotic variance of $\sqrt{n}*hat\mu$ obtained with the CBPS or oCBPS method.
var	The estimated variance of $hat\mu$ obtained with the CBPS or oCBPS method.
std.err	The standard error of $hat\mu$ obtained with the CBPS or oCBPS method.
CI.mu.hat	The confidence interval of $hat\mu$ obtained with the CBPS or oCBPS method with the confidence level specified in the input argument.

## **Examples**

```
#GENERATING THE DATA
n=300
#Initialize the X matrix.
X_v1 \leftarrow rnorm(n, 3, sqrt(2))
X_v2 \leftarrow rnorm(n,0,1)
X_v3 <- rnorm(n, 0, 1)
X_v4 \leftarrow rnorm(n,0,1)
X_{mat} \leftarrow as.matrix(cbind(rep(1,n), X_v1, X_v2, X_v3, X_v4))
\#Initialize the Y_1 and Y_0 vector using the treatment model and the control model.
Y_1 \leftarrow X_mat \%\% matrix(c(200, 27.4, 13.7, 13.7, 13.7), 5, 1) + rnorm(n)
Y_0 \leftarrow X_mat %*% matrix(c(200, 0, 13.7, 13.7, 13.7), 5, 1) + rnorm(n)
#True Propensity Score calculation.
pre_prop <- X_mat[,2:5] %*% matrix(c(0, 0.5, -0.25, -0.1), 4, 1)</pre>
propensity_true <- (exp(pre_prop))/(1+(exp(pre_prop)))</pre>
#Generate T_vec, the treatment vector, with the true propensity scores.
T_vec <- rbinom(n, size=1, prob=propensity_true)</pre>
#Now generate the actual outcome Y_outcome (accounting for treatment/control groups).
Y_{outcome} \leftarrow Y_{1}T_{vec} + Y_{0}(1-T_{vec})
#Use oCBPS.
ocbps.fit <- CBPS(T_vec ~ X_mat, ATT=0, baseline.formula = ~X_mat[,c(1,3:5)],
                  diff.formula = ~X_mat[,2])
#Use the AsyVar function to get the asymptotic variance of the
#estimated average treatment effect and its confidence interval when using oCBPS.
AsyVar(Y=Y_outcome, CBPS_obj=ocbps.fit, method="oCBPS", CI=0.95)
```

balance 5

```
#Use CBPS.
cbps.fit <- CBPS(T_vec ~ X_mat, ATT=0)

#Use the AsyVar function to get the asymptotic variance of the
#estimated average treatment effect and its confidence interval when using CBPS.
AsyVar(Y=Y_outcome, CBPS_obj=cbps.fit, method="CBPS", CI=0.95)</pre>
```

balance

Optimal Covariate Balance

## **Description**

Returns the mean and standardized mean associated with each treatment group, before and after weighting. To access more comprehensive diagnotistics for assessing covariate balance, consider using Noah Greifer's cobalt package.

## Usage

```
balance(object, ...)
```

#### **Arguments**

object A CBPS, npCBPS, or CBMSM object.
... Additional arguments to be passed to balance.

#### **Details**

For binary and multi-valued treatments as well as marginal structural models, each of the matrices' rows are the covariates and whose columns are the weighted mean, and standardized mean associated with each treatment group. The standardized mean is the weighted mean divided by the standard deviation of the covariate for the whole population. For continuous treatments, returns the absolute Pearson correlation between the treatment and each covariate.

### @aliases balance balance.npCBPS balance.CBPS balance.CBMSM

#### Value

Returns a list of two matrices, "original" (before weighting) and "balanced" (after weighting).

#### Author(s)

Christian Fong, Marc Ratkovic, and Kosuke Imai.

	Other parameters to be passed.

Blackwell

Blackwell Data for Covariate Balancing Propensity Score

## Description

This data set gives the outcomes a well as treatment assignments and covariates for the example from Blackwell (2013).

## Format

A data frame consisting of 13 columns (including treatment assignment, time, and identifier vectors) and 570 observations.

#### **Source**

d.gone.neg is the treatment. d.gone.neg.11, d.gone.neg.12, and d.gone.neg.13 are lagged treatment variables. camp.length, deminc, base.poll, base.und, and office covariates. year is the year of the particular race, and time goes from the first measurement (time = 1) to the election (time = 5). demName is the identifier, and demprcnt is the outcome.

Blackwell, Matthew. (2013). A framework for dynamic causal inference in political science. American Journal of Political Science 57, 2, 504-619.

CBIV CBIV

CBIV	Covariate Balancing Propensity Score for Instrumental Variable Estimates (CBIV)

## Description

CBIV estimates propensity scores for compliance status in an instrumental variables setup such that both covariate balance and prediction of treatment assignment are maximized. The method, therefore, avoids an iterative process between model fitting and balance checking and implements both simultaneously.

# Usage

```
CBIV(
   Tr,
   Z,
   X,
   iterations = 1000,
   method = "over",
   twostep = TRUE,
   twosided = TRUE,
   ...
)
```

## Arguments

Tr	A binary treatment variable.
Z	A binary encouragement variable.
X	A pre-treatment covariate matrix.
iterations	An optional parameter for the maximum number of iterations for the optimization. Default is $1000$ .
method	Choose "over" to fit an over-identified model that combines the propensity score and covariate balancing conditions; choose "exact" to fit a model that only contains the covariate balancing conditions. Our simulations suggest that "over" dramatically outperforms "exact."
twostep	Default is TRUE for a two-step GMM estimator, which will run substantially faster than continuous-updating. Set to FALSE to use the continuous-updating GMM estimator.
twosided	Default is TRUE, which allows for two-sided noncompliance with both always-takers and never-takers. Set to FALSE for one-sided noncompliance, which allows only for never-takers.
• • •	Other parameters to be passed through to optim().

CBIV 9

#### **Details**

Fits covariate balancing propensity scores for generalizing local average treatment effect estimates obtained from instrumental variables analysis.

#### Value

coefficients A named matrix of coefficients, where the first column gives the complier coef-

ficients and the second column gives the always-taker coefficients.

fitted.values The fitted N x 3 compliance score matrix. The first column gives the estimated

probability of being a complier, the second column gives the estimated probability of being an always-taker, and the third column gives the estimated probability

of being a never-taker.

weights The optimal weights: the reciprocal of the probability of being a complier.

deviance Minus twice the log-likelihood of the CBIV fit.

converged Convergence value. Returned from the call to optim().

J The J-statistic at convergence

df The number of linearly independent covariates.

bal The covariate balance associated with the optimal weights, calculated as the

GMM loss of the covariate balance conditions.

## **Examples**

```
###
### Example: propensity score matching
### (Need to fix when we have an actual example).
##Load the LaLonde data
data(LaLonde)
## Estimate CBPS
fit <- CBPS(treat ~ age + educ + re75 + re74 +
I(re75==0) + I(re74==0),
data = LaLonde, ATT = TRUE)
summary(fit)</pre>
```

10 CBMSM

## Description

CBMSM estimates propensity scores such that both covariate balance and prediction of treatment assignment are maximized. With longitudinal data, the method returns marginal structural model weights that can be entered directly into a linear model. The method also handles multiple binary treatments administered concurrently.

## Usage

```
CBMSM(
  formula,
  id,
  time,
  data,
  type = "MSM",
  twostep = TRUE,
  msm.variance = "approx",
  time.vary = FALSE,
  init = "opt",
  ...
)
```

## Arguments

formula	A formula of the form treat ~ X. The same covariates are used in each time period. At default values, a single set of coefficients is estimated across all time periods. To allow a different set of coefficients for each time period, set time.vary = TRUE. Data should be sorted by time.	
id	A vector which identifies the unit associated with each row of treat and X.	
time	A vector which identifies the time period associated with each row of treat and X. All data should be sorted by time.	
data	An optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data the variables are taken from environment(formula), typically the environment from which CBMSM is called. Data should be sorted by time.	
type	"MSM" for a marginal structural model, with multiple time periods or "Multi-Bin" for multiple binary treatments at the same time period.	
twostep	Set to TRUE to use a two-step estimator, which will run substantially faster than continuous-updating. Default is FALSE, which uses the continuous-updating estimator described by Imai and Ratkovic (2014).	
msm.variance	Default is FALSE, which uses the low-rank approximation of the variance described in Imai and Ratkovic (2014). Set to TRUE to use the full variance matrix.	

CBMSM 11

time.vary Default is FALSE, which uses the same coefficients across time period. Set to

TRUE to fit one set per time period.

init Default is "opt", which uses CBPS and logistic regression starting values, and

chooses the one that achieves the best balance. Other options are "glm" and

"CBPS"

... Other parameters to be passed through to optim()

#### **Details**

Fits covariate balancing propensity scores for marginal structural models.

### @aliases CBMSM CBMSM.fit

#### Value

weights The optimal weights.

fitted.values The fitted propensity score for each observation.

y The treatment vector used.

x The covariate matrix.

id The vector id used in CBMSM.fit.time The vector time used in CBMSM.fit.

model The model frame.
call The matched call.

formula The formula supplied.

data The data argument.

treat.hist A matrix of the treatment history, with each observation in rows and time in

columns.

treat.cum A vector of the cumulative treatment history, by individual.

  X,
  id,
  time,
  MultiBin.fit,
  twostep,
  msm.variance,
```

CBPS CBPS

```
time.vary,
init,
...
)
```

## Arguments

treat	A vector of treatment assignments. For N observations over T time periods, the length of treat should be N*T.
X	A covariate matrix. For N observations over T time periods, X should have $N*T$ rows.
id	A vector which identifies the unit associated with each row of treat and X.
time	A vector which identifies the time period associated with each row of treat and X.
MultiBin.fit	A parameter for whether the multiple binary treatments occur concurrently (FALSE) or over consecutive time periods (TRUE) as in a marginal structural model. Setting type = "MultiBin" when calling CBMSM will set MultiBin.fit to TRUE when CBMSM.fit is called.
twostep	Set to TRUE to use a two-step estimator, which will run substantially faster than continuous-updating. Default is FALSE, which uses the continuous-updating estimator described by Imai and Ratkovic (2014).
msm.variance	Default is FALSE, which uses the low-rank approximation of the variance described in Imai and Ratkovic (2014). Set to TRUE to use the full variance matrix.
time.vary	Default is FALSE, which uses the same coefficients across time period. Set to TRUE to fit one set per time period.
init	Default is "opt", which uses CBPS and logistic regression starting values, and chooses the one that achieves the best balance. Other options are "glm" and "CBPS"
• • •	Other parameters to be passed through to optim()

Covariate Balancing Propensity Score (CBPS) Estimation

# Description

**CBPS** 

CBPS estimates propensity scores such that both covariate balance and prediction of treatment assignment are maximized. The method, therefore, avoids an iterative process between model fitting and balance checking and implements both simultaneously. For cross-sectional data, the method can take continuous treatments and treatments with a control (baseline) condition and either 1, 2, or 3 distinct treatment conditions.

Fits covariate balancing propensity scores.

### @aliases CBPS CBPS.fit print.CBPS

#### Usage

```
CBPS(
  formula,
  data,
  na.action,
  ATT = 1,
  iterations = 1000,
  standardize = TRUE,
  method = "over",
  twostep = TRUE,
  sample.weights = NULL,
  baseline.formula = NULL,
  diff.formula = NULL,
  ...
)
```

#### **Arguments**

formula An object of class formula (or one that can be coerced to that class): a symbolic

description of the model to be fitted.

data An optional data frame, list or environment (or object coercible by as.data.frame

to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment (formula), typically the environment

from which CBPS is called.

na.action A function which indicates what should happen when the data contain NAs. The

default is set by the na.action setting of options, and is na.fail if that is unset.

ATT Default is 1, which finds the average treatment effect on the treated interpreting

the second level of the treatment factor as the treatment. Set to 2 to find the ATT interpreting the first level of the treatment factor as the treatment. Set to 0 to find the average treatment effect. For non-binary treatments, only the ATE is

available.

iterations An optional parameter for the maximum number of iterations for the optimiza-

tion. Default is 1000.

standardize Default is TRUE, which normalizes weights to sum to 1 within each treatment

group. For continuous treatments, normalizes weights to sum up to 1 for the

entire sample. Set to FALSE to return Horvitz-Thompson weights.

method Choose "over" to fit an over-identified model that combines the propensity score

and covariate balancing conditions; choose "exact" to fit a model that only con-

tains the covariate balancing conditions.

twostep Default is TRUE for a two-step estimator, which will run substantially faster than

continuous-updating. Set to FALSE to use the continuous-updating estimator

described by Imai and Ratkovic (2014).

sample.weights Survey sampling weights for the observations, if applicable. When left NULL,

defaults to a sampling weight of 1 for each observation.

baseline.formula

Used only to fit iCBPS (see Fan et al). Currently only works with binary treatments. A formula specifying the balancing covariates in the baseline outcome

model, i.e., E(Y(0)|X).

diff.formula Used only to fit iCBPS (see Fan et al). Currently only works with binary treat-

ments. A formula specifying the balancing covariates in the difference between

the treatment and baseline outcome model, i.e., E(Y(1)-Y(0)|X).

Other parameters to be passed through to optim().

#### Value

fitted.values The fitted propensity score

linear.predictor

X \* beta

deviance Minus twice the log-likelihood of the CBPS fit

weights

The optimal weights. Let  $\pi_i=f(T_i|X_i)$ . For binary ATE, these are given by  $\frac{T_i}{\pi_i}+\frac{(1-T_i)}{(1-\pi_i)}$ . For binary ATT, these are given by  $\frac{n}{n_t}*\frac{T_i-\pi_i}{1-\pi_i}$ . For multi\_valued

treatments, these are given by  $\sum_{j=0}^{J-1} T_{i,j}/\pi_{i,j}$ . For continuous treatments, these are given by  $\frac{f(T_i)}{f(T_i|X_i)}$ . These expressions for weights are all before standardization (i.e. with standardize=FALSE). Standardization will make weights sum to 1 within each treatment group. For continuous treatment, standardization will

make all weights sum to 1. If sampling weights are used, the weight for each

observation is multiplied by the survey sampling weight.

The treatment vector used У

The covariate matrix Х

model The model frame

Convergence value. Returned from the call to optim(). converged

call The matched call

formula The formula supplied data The data argument

A named vector of coefficients coefficients

sigmasq The sigma-squared value, for continuous treatments only

J The J-statistic at convergence

The J-statistic for the parameters from maximum likelihood estimation mle.J

var The covariance matrix for the coefficients.

Ttilde For internal use only. Xtilde For internal use only. beta.tilde For internal use only. For internal use only. simgasq.tilde

CBPS.fit

CBPS.fit determines the proper routine (what kind of treatment) and calls the approporiate function. It also pre- and post-processes the data

## Description

CBPS.fit determines the proper routine (what kind of treatment) and calls the approporiate function. It also pre- and post-processes the data

## Usage

```
CBPS.fit(
   treat,
   X,
   baselineX,
   diffX,
   ATT,
   method,
   iterations,
   standardize,
   twostep,
   sample.weights = sample.weights,
   ...
)
```

## Arguments

treat A vector of treatment assignments. Binary or multi-valued treatments should be

factors. Continuous treatments should be numeric.

X A covariate matrix.

baselineX Similar to baseline. formula, but in matrix form.

diffX Similar to diff. formula, but in matrix form.

ATT Default is 1, which finds the average treatment effect on the treated interpreting

the second level of the treatment factor as the treatment. Set to 2 to find the ATT interpreting the first level of the treatment factor as the treatment. Set to 0 to find the average treatment effect. For non-binary treatments, only the ATE is

available.

method Choose "over" to fit an over-identified model that combines the propensity score

and covariate balancing conditions; choose "exact" to fit a model that only con-

tains the covariate balancing conditions.

iterations An optional parameter for the maximum number of iterations for the optimiza-

tion. Default is 1000.

20 hdCBPS

Default is TRUE, which normalizes weights to sum to 1 within each treatment group. For continuous treatments, normalizes weights to sum up to 1 for the entire sample. Set to FALSE to return Horvitz-Thompson weights.

Default is TRUE for a two-step estimator, which will run substantially faster than continuous-updating. Set to FALSE to use the continuous-updating estimator described by Imai and Ratkovic (2014).

Sample.weights

Survey sampling weights for the observations, if applicable. When left NULL, defaults to a sampling weight of 1 for each observation.

Other parameters to be passed through to optim().

#### Value

CBPS.fit object

hdCBPS high dimensional CBPS method to parses the formula object

and passes the result to hdCBPS.fit, which calculates ATE using CBPS

method in a high dimensional setting.

## Description

hdCBPS high dimensional CBPS method to parses the formula object and passes the result to hd-CBPS.fit, which calculates ATE using CBPS method in a high dimensional setting.

## Usage

```
hdCBPS(
  formula,
  data,
  na.action,
  y,
  ATT = 0,
  iterations = 1000,
  method = "linear"
)
```

#### **Arguments**

formula An object of class formula (or one that can be coerced to that class): a symbolic

description of the model to be fitted.

data An optional data frame, list or environment (or object coercible by as.data.frame

to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from

which CBPS is called.

na.action A function which indicates what should happen when the data contain NAs. The

default is set by the na.action setting of options, and is na.fail if that is unset.

LaLonde 21

y An outcome variable.

ATT Option to calculate ATT

iterations An optional parameter for the maximum number of iterations for the optimiza-

tion. Default is 1000.

method Choose among "linear", "binomial", and "possion".

#### Value

ATT Average treatment effect on the treated.

ATE Average treatment effect.

s Standard Error.

fitted.values The fitted propensity score

coefficients1 Coefficients for the treated propensity score coefficients0 Coefficients for the untreated propensity score

model The model frame

LaLonde Data for Covariate Balancing Propensity Score

## **Description**

This data set gives the outcomes a well as treatment assignments and covariates for the econometric evaluation of training programs in LaLonde (1986).

#### **Format**

A data frame consisting of 12 columns (including a treatment assignment vector) and 3212 observations.

#### Source

Data from the National Supported Work Study. A benchmark matching dataset. Columns consist of an indicator for whether the observed unit was in the experimental subset; an indicator for whether the individual received the treatment; age in years; schooling in years; indicators for black and Hispanic; an indicator for marriage status, one of married; an indicator for no high school degree; reported earnings in 1974, 1975, and 1978; and whether the 1974 earnings variable is missing. Data not missing 1974 earnings are the Dehejia-Wahba subsample of the LaLonde data. Missing values for 1974 earnings set to zero. 1974 and 1975 earnings are pre-treatment. 1978 earnings is taken as the outcome variable.

npCBPS	Non-Parametric Covariate Balancing Propensity Score (npCBPS) Estimation

## **Description**

npCBPS is a method to estimate weights interpretable as (stabilized) inverse generlized propensity score weights,  $w_i = f(T_i)/f(T_i|X)$ , without actually estimating a model for the treatment to arrive at f(T|X) estimates. In brief, this works by maximizing the empirical likelihood of observing the values of treatment and covariates that were observed, while constraining the weights to be those that (a) ensure balance on the covariates, and (b) maintain the original means of the treatment and covariates.

In the continuous treatment context, this balance on covariates means zero correlation of each covariate with the treatment. In binary or categorical treatment contexts, balance on covariates implies equal means on the covariates for observations at each level of the treatment. When given a numeric treatment the software handles it continuously. To handle the treatment as binary or categorical is must be given as a factor.

Furthermore, we apply a Bayesian variant that allows the correlation of each covariate with the treatment to be slightly non-zero, as might be expected in a a given finite sample.

Estimates non-parametric covariate balancing propensity score weights.

### @aliases npCBPS npCBPS.fit

#### Usage

```
npCBPS(formula, data, na.action, corprior = 0.01, print.level = 0, ...)
```

#### **Arguments**

formula	An object of class formula (or one that can be coerced to that class): a symbolic description of the model to be fitted.	
data	An optional data frame, list or environment (or object coercible by as.data.fr to a data frame) containing the variables in the model. If not found in the variables are taken from environment(formula), typically the environ- from which CBPS is called.	
na.action	A function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset.	
corprior	corprior Prior hyperparameter controlling the expected amount of correlation between covariate and the treatment. Specifically, the amount of correlation between the k-dimensional covariates, X, and the treatment T after weighting is assute to have prior distribution MVN(0,sigma^2 I_k). We conceptualize sigma^4	

npCBPS 23

a tuning parameter to be used pragmatically. It's default of 0.1 ensures that the balance constraints are not too harsh, and that a solution is likely to exist. Once the algorithm works at such a high value of sigma^2, the user may wish to attempt values closer to 0 to get finer balance.

print.level

Controls verbosity of output to the screen while npCBPS runs. At the default of print.level=0, little output is produced. It print.level>0, it outputs diagnostics including the log posterior (log\_post), the log empirical likelihood associated with the weights (log\_el), and the log prior probability of the (weighted) correlation of treatment with the covariates.

... Other parameters to be passed.

#### Value

weights The optimal weights у The treatment vector used The covariate matrix Х The model frame model call The matched call formula The formula supplied data The data argument The log density for the (weighted) correlation of the covariates with the treatlog.p.eta ment, given the choice of prior (corprior) log.el The log empirical likelihood of the observed data at the chosen set of IPW eta A vector describing the correlation between the treatment and each covariate on the weighted data at the solution. The sum of weights, provided as a check on convergence. This is always 1 sumw0 when convergence occurs unproblematically. If it differs from 1 substantially, no solution perfectly satisfying the conditions was found, and the user may consider

```

npCBPS.fit

npCBPS.fit

## **Description**

npCBPS.fit

## Usage

```
npCBPS.fit(treat, X, corprior, print.level, ...)
```

## Arguments

treat

A vector of treatment assignments. Binary or multi-valued treatments should be factors. Continuous treatments should be numeric.

Χ

A covariate matrix.

corprior

Prior hyperparameter controlling the expected amount of correlation between each covariate and the treatment. Specifically, the amount of correlation between the k-dimensional covariates, X, and the treatment T after weighting is assumed to have prior distribution MVN(0,sigma^2 I\_k). We conceptualize sigma^2 as a tuning parameter to be used pragmatically. It's default of 0.1 ensures that the balance constraints are not too harsh, and that a solution is likely to exist. Once the algorithm works at such a high value of sigma^2, the user may wish to attempt values closer to 0 to get finer balance.

print.level

Controls verbosity of output to the screen while npCBPS runs. At the default of print.level=0, little output is produced. It print.level>0, it outputs diagnostics including the log posterior (log\_post), the log empirical likelihood associated with the weights (log\_el), and the log prior probability of the (weighted) correlation of treatment with the covariates.

.. Other parameters to be passed.

plot.CBMSM 25

plot.CBMSM Plotting CBPS Estimation for Marginal Str	uctural Models
--	----------------

# Description

Plots the absolute difference in standardized means before and after weighting.

## Usage

```
## S3 method for class 'CBMSM'
plot(x, covars = NULL, silent = TRUE, boxplot = FALSE, ...)
```

## **Arguments**

X	an object of class "CBMSM".
covars	Indices of the covariates to be plotted (excluding the intercept). For example, if only the first two covariates from balance are desired, set covars to 1:2. The default is NULL, which plots all covariates.
silent	If set to FALSE, returns the absolute imbalance for each treatment history pair before and after weighting. This helps the user to create his or her own customized plot. Default is TRUE, which returns nothing.
boxplot	If set to TRUE, returns a boxplot summarizing the imbalance on the covariates instead of a point for each covariate. Useful if there are many covariates.
	Additional arguments to be passed to plot.

## **Details**

Covariate balance is improved if the plot's points are below the plotted line of y=x.

#### Value

The x-axis gives the imbalance for each covariate-treatment history pair without any weighting, and the y-axis gives the imbalance for each covariate-treatment history pair after CBMSM weighting. Imbalance is measured as the absolute difference in standardized means for the two treatment histories. Means are standardized by the standard deviation of the covariate in the full sample.

26 plot.CBPS

plot.CBPS	Plotting Covariate Balancing Propensity Score Estimation

## **Description**

This function plots the absolute difference in standardized means before and after weighting. To access more sophisticated graphics for assessing covariate balance, consider using Noah Greifer's cobalt package.

## Usage

```
## S3 method for class 'CBPS'
plot(x, covars = NULL, silent = TRUE, boxplot = FALSE, ...)
```

#### **Arguments**

x	an object of class "CBPS" or "npCBPS", usually, a result of a call to CBPS or npCBPS.
covars	Indices of the covariates to be plotted (excluding the intercept). For example, if only the first two covariates from balance are desired, set covars to 1:2. The default is NULL, which plots all covariates.
silent	If set to FALSE, returns the imbalances used to construct the plot. Default is TRUE, which returns nothing.
boxplot	If set to TRUE, returns a boxplot summarizing the imbalance on the covariates instead of a point for each covariate. Useful if there are many covariates.
	Additional arguments to be passed to plot.

#### **Details**

The "Before Weighting" plot gives the balance before weighting, and the "After Weighting" plot gives the balance after weighting.

```
### @aliases plot.CBPS plot.npCBPS
```

## Value

For binary and multi-valued treatments, plots the absolute difference in standardized means by contrast for all covariates before and after weighting. This quantity for a single covariate and a given pair of treatment conditions is given by  $\frac{\sum_{i=1}^n w_i * (T_i = 1) * X_i}{\sum_{i=1}^n (T_i = 1) * w_i} - \frac{\sum_{i=1}^n w_i * (T_i = 0) * X_i}{\sum_{i=1}^n (T_i = 0) * w_i}.$  For continuous treatments, plots the weighted absolute Pearson correlation between the treatment and each covariate. See https://en.wikipedia.org/wiki/Pearson\_product-moment\_correlation\_coefficient# Weighted\_correlation\_coefficient.

vcov\_outcome

Calculate Variance-Covariance Matrix for Outcome Model

## **Description**

vcov\_outcome Returns the variance-covariance matrix of the main parameters of a fitted CBPS object.

This adjusts the standard errors of the weighted regression of Y on Z for uncertainty in the weights. ### @aliases vcov\_outcome vcov\_outcome.CBPSContinuous

## Usage

```
vcov_outcome(object, Y, Z, delta, tol = 10^(-5), lambda = 0.01)
```

vcov\_outcome 31

## **Arguments**

object	A fitted CBPS object.
Υ	The outcome.
Z	The covariates (including the treatment and an intercept term) that predict the outcome.
delta	The coefficients from regressing Y on Z, weighting by the cbpsfit\$weights.
tol	Tolerance for choosing whether to improve conditioning of the "M" matrix prior to conversion. Equal to $1/(condition\ number)$ , i.e. the smallest eigenvalue divided by the largest.
lambda	The amount to be added to the diagonal of M if the condition of the matrix is worse than tol.

#### Value

A matrix of the estimated covariances between the parameter estimates in the weighted outcome regression, adjusted for uncertainty in the weights.

## Author(s)

Christian Fong, Chad Hazlett, and Kosuke Imai.

## References

Lunceford and Davididian 2004.
