Type Package
Title An R Package for Multiple Break-Point Detection via the
Cross-Entropy Method
Version 1.2
<b>Date</b> 2016-01-11
Author Priyadarshana W.J.R.M. and Georgy Sofronov
Maintainer Priyadarshana W.J.R.M. <mjayawardana@swin.edu.au></mjayawardana@swin.edu.au>
<b>Description</b> Implements the Cross-Entropy (CE) method, which is a model based stochastic optimization technique to estimate both the number and their corresponding locations of breakpoints in continuous and discrete measurements (Priyadarshana and Sofronov (2015), Priyadarshana and Sofronov (2012a), Priyadarshana and Sofronov (2012b)).

breakpoint-package Multiple Break-Point Detection via the Cross-Entropy Method

## **Description**

The breakpoint package implements variants of the Cross-Entropy (CE) method proposed in Priyadarshana and Sofronov (2015, 2012a and 2012b) to estimate both the number and the corresponding locations of break-points in biological sequences of continuous and discrete measurements. The proposed method primarily built to detect multiple break-points in genomic sequences. However, it can be easily extended and applied to other problems.

#### **Details**

Package: breakpoint
Type: Package
Version: 1.2
Date: 2016-01-11

License: GPL 2.0

"breakpoint"" package provides estimates on both the number as well as the corresponding locations of break-points. The algorithms utilize the Cross-Entropy (CE) method, which is a model-based stochastic optimization procedure to obtain the estimates on locations. Model selection procedures are used to obtain the number of break-points. Current implementation of the methodology works as an exact search method in estimating the number of break-points. However, it supports calculations if the initial locations are provided. A parallel implementation of the procedures can be carried-out in Unix/Linux/MAC OSX and WINDOWS OS with the use of "parallel" and "doParallel" packages.

CE.NB	Multiple Break-point Detection via the CE Method with Negative Bi-
	nomial Distribution

## **Description**

Performs calculations to estimate both the number of break-points and their corresponding locations of discrete measurements with the CE method. Negative binomial distribution is used to model the over-dispersed discrete (count) data. This function supports for the simulation of break-point locations in the CE algorithm based on the four parameter beta distribution or truncated normal distribution. User can select either BIC or AIC to select the optimal number of break-points.

#### Usage

```
CE.NB(data, Nmax = 10, eps = 0.01, rho = 0.05, M = 200, h = 5, a = 0.8, b = 0.8, distyp = 1, penalty = "BIC", parallel = FALSE)
```

data	data to be analysed. A single column array or a dataframe.
Nmax	maximum number of break-points. Default value is 10.
eps	the cut-off value for the stopping criterion in the CE method. Default value is $0.01$ .
rho	the fraction which is used to obtain the best performing set of sample solutions (i.e., elite sample). Default value is $0.05$ .
М	sample size to be used in simulating the locations of break-points. Default value is 200.
h	minimum aberration width. Default is 5.
a	a smoothing parameter value. It is used in the four parameter beta distribution to smooth both shape parameters. When simulating from the truncated normal distribution, this value is used to smooth the estimates of the mean values. Default is 0.8.
b	a smoothing parameter value. It is used in the truncated normal distribution to smooth the estimates of the standard deviation. Default is 0.8.
distyp	distribution to simulate break-point locations. Options: $1 = \text{four parameter beta}$ distribution, $2 = \text{truncated normal distribution}$ . Default is 1.

4 CE.NB

penalty User can select either BIC or AIC to obtain the number of break-points. Options:

"BIC", "AIC". Default is "BIC".

parallel A logical argument specifying if parallel computation should be carried-out

(TRUE) or not (FALSE). By default it is set as 'FALSE'. In WINDOWS OS systems "snow" functionalities are used, whereas in Unix/Linux/MAC OSX "multicore" functionalities are used to carryout parallel computations with the

maximum number of cores available.

#### **Details**

The negative binomial (NB) distribution is used to model the discrete (count) data. NB model is preferred over the Poission model when over-dispersion is observed in the count data. A performance function score (BIC or AIC) is calculated for each of the solutions generated by the statistical distribution (four parameter beta distribution or truncated normal distribution), which is used to simulate break-points from no break-point to the user provided maximum number of break-points (default is 10). The solution that minimizes the BIC/AIC with respect to the number of break-points is reported as the optimal solution. Finally, a list containing a vector of break-point locations, number of break-points, BIC/AIC values and log-likelihood value is returned in the console.

#### Value

A list is returned with following items:

No.BPs The number of break-points in the data that is estimated by the CE method

BP.Loc A vector of break-point locations

BIC/AIC BIC/AIC value

11 Loglikelihood of the optimal solution

```

CE.NB.Init

Multiple Break-point Detection via the CE Method with Negative Binomial Distribution with initial locations

## **Description**

Performs calculations to estimate the break-point locations when their initial values are given. Negative binomial distribution is used to model the over-dispersed discrete (count) data. This function supports for the simulation of break-point locations in the CE algorithm based on the four parameter beta distribution or truncated normal distribution. User can select either BIC or AIC to select the optimal number of break-points.

CE.NB.Init

## Usage

```
CE.NB.Init(data, init.locs, eps = 0.01, rho = 0.05, M = 200, h = 5, a = 0.8, b = 0.8, distyp = 1, penalty = "BIC", var.init = 1e+05, parallel = FALSE)
```

### **Arguments**

data	data to be analysed. A single column array or a dataframe.
init.locs	Initial break-point locations.
eps	the cut-off value for the stopping criterion in the CE method. Default value is $0.01.$
rho	the fraction which is used to obtain the best performing set of sample solutions (i.e., elite sample). Default value is $0.05$ .
М	sample size to be used in simulating the locations of break-points. Default value is $200$ .
h	minimum aberration width. Default is 5.
a	a smoothing parameter value. It is used in the four parameter beta distribution to smooth both shape parameters. When simulating from the truncated normal distribution, this value is used to smooth the estimates of the mean values. Default is $0.8$ .
b	a smoothing parameter value. It is used in the truncated normal distribution to smooth the estimates of the standard deviation. Default is $0.8$ .
distyp	distribution to simulate break-point locations. Options: $1 =$ four parameter beta distribution, $2 =$ truncated normal distribution. Default is 1.
penalty	User can select either BIC or AIC to obtain the number of break-points. Options: "BIC", "AIC". Default is "BIC".
var.init	Initial variance value to facilitate the search process. Default is 100000.
parallel	A logical argument specifying if parallel computation should be carried-out (TRUE) or not (FALSE). By default it is set as 'FALSE'. In WINDOWS OS systems "snow" functionalities are used, whereas in Unix/Linux/MAC OSX "multicore" functionalities are used to carryout parallel computations with the maximum number of cores available.

## **Details**

The negative binomial (NB) distribution is used to model the discrete (count) data. NB model is preferred over the Poission model when over-dispersion is observed in the count data. A performance function score (BIC or AIC) is calculated for each of the solutions generated by the statistical distribution (four parameter beta distribution or truncated normal distribution) with respect to the user provided initial locations. Finally, a list containing a vector of break-point locations, number of break-points, BIC/AIC values and log-likelihood value is returned in the console.

### Value

A list is returned with following items:

No.BPs The number of break-points

CE.NB.Init 7

BP.Loc A vector of break-point locations

BIC/AIC BIC/AIC value

11 Loglikelihood of the optimal solution

```

CE.Normal.Init.Mean

Multiple break-point detection via the CE method for continuous data with initial locations (mean levels)

## **Description**

Performs calculations to estimate the break-point locations when their initial values are given. Normal distribution is used to model the observed continous data. Accross the segments standard deviation is assumed to be the same. This function supports for the simulation of break-point locations based on the four parameter beta distribution or truncated normal distribution. User can select from the modified BIC (mBIC) proposed by Zhang and Siegmund (2007), BIC or AIC to obtain the optimal number of break-points.

#### Usage

```
CE.Normal.Init.Mean(data, init.locs, eps = 0.01, rho = 0.05, M = 200, h = 5, a = 0.8, b = 0.8, distyp = 1, penalty = "mBIC", var.init = 1e+05, parallel = FALSE)
```

data	data to be analysed. A single column array or a dataframe.
init.locs	Initial break-point locations.
eps	the cut-off value for the stopping criterion in the CE method. Default value is 0.01.
rho	the fraction which is used to obtain the best performing set of sample solutions (i.e., elite sample). Default value is 0.05.
М	sample size to be used in simulating the locations of break-points. Default value is 200.
h	minimum aberration width. Default is 5.

CE.Normal.Init.Mean 9

a	a smoothing parameter value. It is used in the four parameter beta distribution to smooth both shape parameters. When simulating from the truncated normal distribution, this value is used to smooth the estimates of the mean values. Default is 0.8.
b	a smoothing parameter value. It is used in the truncated normal distribution to smooth the estimates of the standard deviation. Default is 0.8.
distyp	distribution to simulate break-point locations. Options: $1 =$ four parameter beta distribution, $2 =$ truncated normal distribution. Default is 1.
penalty	User can select from mBIC, BIC or AIC to obtain the optimal number of breakpoints. Options: "mBIC", "BIC" and "AIC". Default is "mBIC".
var.init	Initial variance value to facilitate the search process. Default is 100000.
parallel	A logical argument specifying if parallel computation should be carried-out (TRUE) or not (FALSE). By default it is set as 'FALSE'. In WINDOWS OS systems "snow" functionalities are used, whereas in Unix/Linux/MAC OSX "multicore" functionalities are used to carryout parallel computations with the maximum number of cores available.

#### **Details**

The normal distribution is used to model the continuous data. A performance function score (mBIC/BIC/AIC) is calculated for each of the solutions generated by the statistical distribution (four parameter beta distribution or truncated normal distribution), which is used to simulate break-points from the user provided initial locations. The solution that maximizes the selection criteria with respect to the number of break-points is reported as the optimal solution. Finally, a list containing a vector of break-point locations, number of break-points, mBIC/BIC/AIC values and log-likelihood value is returned in the console.

## Value

A list is returned with following items:

No.BPs The number of break-points

BP.Loc A vector of break-point locations

mBIC/BIC/AIC mBIC/BIC/AIC value

11 Loglikelihood of the optimal solution

CE.Normal.Init.MeanVar

Multiple break-point detection via the CE method for continuous data with initial locations (both mean and variance changes)

## **Description**

Performs calculations to estimate the break-point locations when their initial values are given. The normal distribution is used to model the observed continous data. Both changes in mean and variance are estimated. This function supports for the simulation of break-point locations based on the four parameter beta distribution or truncated normal distribution. User can select either from the general BIC or AIC to obtain the optimal number of break-points.

#### Usage

```
CE.Normal.Init.MeanVar(data, init.locs, eps = 0.01, rho = 0.05, M = 200, h = 5, a = 0.8, b = 0.8, distyp = 1, penalty = "BIC", var.init = 1e+05, parallel = FALSE)
```

```

data	data to be analysed. A single column array or a dataframe.
Nmax	maximum number of break-points. Default value is 10.
eps	the cut-off value for the stopping criterion in the CE method. Default value is $0.01$ .
rho	the fraction which is used to obtain the best performing set of sample solutions (i.e., elite sample). Default value is 0.05.
М	sample size to be used in simulating the locations of break-points. Default value is 200.
h	minimum aberration width. Default is 5.
а	a smoothing parameter value. It is used in the four parameter beta distribution to smooth both shape parameters. When simulating from the truncated normal distribution, this value is used to smooth the estimates of the mean values. Default is 0.8.
b	a smoothing parameter value. It is used in the truncated normal distribution to smooth the estimates of the standard deviation. Default is 0.8.
distyp	distributions to simulate break-point locations. Options: $1 = \text{four parameter beta}$ distribution, $2 = \text{truncated normal distribution}$ . Default is 1.
penalty	User can select from mBIC, BIC or AIC to obtain the optimal number of breakpoints. Options: "mBIC", "BIC" and "AIC". Default is "mBIC".
parallel	A logical argument specifying if parallel computation should be carried-out (TRUE) or not (FALSE). By default it is set as 'FALSE'. In WINDOWS OS systems "snow" functionalities are used, whereas in Unix/Linux/MAC OSX "multicore" functionalities are used to carryout parallel computations with the maximum number of cores available.

14 CE.Normal.Mean

#### **Details**

The normal distribution is used to model the continuous data. A performance function score (mBIC/BIC/AIC) is calculated for each of the solutions generated by the statistical distribution (four parameter beta distribution or truncated normal distribution), which is used to simulate breakpoints from no break-point to the user provided maximum number of break-points. The solution that maximizes the selection criteria with respect to the number of break-points is reported as the optimal solution. Finally, a list containing a vector of break-point locations, number of break-points, mBIC/BIC/AIC values and log-likelihood value is returned in the console.

#### Value

A list is returned with following items:

No.BPs The number of break-points

BP.Loc A vector of break-point locations

mBIC/BIC/AIC mBIC/BIC/AIC value

11 Loglikelihood of the optimal solution

CE.Normal.MeanVar

### **Examples**

```
data(ch1.GM03563)
## Not run:
## CE with four parameter beta distribution with mBIC as the selection criterion ##
obj1 <- CE.Normal.Mean(ch1.GM03563, distyp = 1, penalty = "mBIC", parallel =TRUE)
profilePlot(obj1, simdata)

## CE with truncated normal distribution with mBIC as the selection criterion ##
obj2 <- CE.Normal.Mean(ch1.GM03563, distyp = 2, penalty = "mBIC", parallel =TRUE)
profilePlot(obj2, simdata)

## End(Not run)</pre>
```

CE.Normal.MeanVar

Multiple break-point detection via the CE method for continuous data (both mean and variance changes)

## **Description**

This function performs calculations to estimate both the number of break-points and their corresponding locations of continuous measurements with the CE method. The normal distribution is used to model the observed continuous data. This function supports for the simulation of break-point locations based on the four parameter beta distribution or truncated normal distribution. User can select either from the genral BIC or AIC to obtain the optimal number of break-points.

### Usage

```
CE.Normal.MeanVar(data, Nmax = 10, eps = 0.01, rho = 0.05, M = 200, h = 5, a = 0.8, b = 0.8, distyp = 1, distyp = 1
```

data	data to be analysed. A single column array or a dataframe.
Nmax	maximum number of break-points. Default value is 10.
eps	the cut-off value for the stopping criterion in the CE method. Default value is $0.01$ .
rho	the fraction which is used to obtain the best performing set of sample solutions (i.e., elite sample). Default value is 0.05.
М	sample size to be used in simulating the locations of break-points. Default value is 200.
h	minimum aberration width. Default is 5.
a	a smoothing parameter value. It is used in the four parameter beta distribution to smooth both shape parameters. When simulating from the truncated normal distribution, this value is used to smooth the estimates of the mean values. Default is 0.8.

16 CE.Normal.MeanVar

b a smoothing parameter value. It is used in the truncated normal distribution to

smooth the estimates of the standard deviation. Default is 0.8.

distributions to simulate break-point locations. Options: 1 = four parameter beta

distribution, 2 = truncated normal distribution. Default is 1.

penalty User can select from BIC or AIC to obtain the optimal number of break-points.

Options: "BIC" and "AIC". Default is "BIC".

parallel A logical argument specifying if parallel computation should be carried-out

(TRUE) or not (FALSE). By default it is set as 'FALSE'. In WINDOWS OS systems "snow" functionalities are used, whereas in Unix/Linux/MAC OSX "multicore" functionalities are used to carryout parallel computations with the

maximum number of cores available.

#### **Details**

The normal distribution is used to model the continuous data. A performance function score (BIC/AIC) is calculated for each of the solutions generated by the statistical distribution (four parameter beta distribution or truncated normal distribution), which is used to simulate break-points from no break-point to the user provided maximum number of break-points. Changes in both mean and variance are estimated. The solution that maximizes the selection criteria with respect to the number of break-points is reported as the optimal solution. Finally, a list containing a vector of break-point locations, number of break-points, BIC/AIC values and log-likelihood value is returned in the console.

#### Value

A list is returned with following items:

No.BPs The number of break-points

BP.Loc A vector of break-point locations

BIC/AIC BIC/AIC value

11 Loglikelihood of the optimal solution

CE.ZINB

Multiple Break-point Detection via the CE Method with Zero-Inflated Negative Binomial Distribution

## Description

Performs calculations to estimate both the number of break-points and their corresponding locations of discrete measurements with the CE method. Zero-inflated negative binomial distribution is used to model the excess zero observations and to model over-dispersesion in the oberved discrete (count) data. This function supports for the simulation of break-point locations in the CE algorithm based on the four parameter beta distribution and truncated normal distribution. The general BIC or AIC can be used to select the optimal number of break-points.

## Usage

```
CE.ZINB(data, Nmax = 10, eps = 0.01, rho = 0.05, M = 200, h = 5, a = 0.8, b = 0.8, distyp = 1, penalty = "BIC", parallel = FALSE)
```

18 CE.ZINB

## **Arguments**

data	data to be analysed. A single column array or a dataframe.
Nmax	maximum number of break-points. Default value is 10.
eps	the cut-off value for the stopping criterion in the CE method. Default value is $0.01$ .
rho	the fraction which is used to obtain the best performing set of sample solutions (i.e., elite sample). Default value is 0.05.
М	sample size to be used in simulating the locations of break-points. Default value is 200.
h	minimum aberration width. Default is 5.
a	a smoothing parameter value. It is used in the four parameter beta distribution to smooth both shape parameters. When simulating from the truncated normal distribution, this value is used to smooth the estimates of the mean values. Default is 0.8.
b	a smoothing parameter value. It is used in the truncated normal distribution to smooth the estimates of the standard deviation. Default is 0.8.
distyp	distribution to simulate break-point locations. Options: $1 =$ four parameter beta distribution, $2 =$ truncated normal distribution. Default is 1.
penalty	User can select either BIC or AIC to obtain the number of break-points. Options: "BIC", "AIC". Default is "BIC".
parallel	A logical argument specifying if parallel computation should be carried-out (TRUE) or not (FALSE). By default it is set as 'FALSE'. In WINDOWS OS systems "snow" functionalities are used, whereas in Unix/Linux/MAC OSX "multicore" functionalities are used to carryout parallel computations with the maximum number of cores available.

## **Details**

Zero-inflated negative binomial (ZINB) distribution is used to model the discrete (count) data. ZINB model is preferred over the NB model when both excess zero values and over-dispersion observed in the count data. A performance function score (BIC) is calculated for each of the solutions generated by the statistical distribution (four parameter beta distribution or truncated normal distribution), which is used to simulate break-points from no break-point to the user provided maximum number of break-points. The solution that minimizes the BIC/AIC with respect to the number of break-points is reported as the optimal solution. Finally, a list containing a vector of break-point, BIC/AIC values and log-likelihood value is returned in the console.

#### Value

A list is returned with following items:

No.BPs	The number of break-points
BP.Loc	A vector of break-point locations
BIC/AIC	BIC/AIC value

11 Loglikelihood of the optimal solution

```

CE.ZINB.Init

Multiple Break-point Detection via the CE Method with Zero-Inflated Negative Binomial Distribution with initial locations

## **Description**

Performs calculations to estimate the break-point locations when their initial values are given. Zero-inflated negative binomial distribution is used to model the excess zero observations and to model over-dispersesion in the oberved discrete (count) data. This function supports for the simulation of break-point locations in the CE algorithm based on the four parameter beta distribution and truncated normal distribution. The general BIC or AIC can be used to select the optimal number of break-points.

#### Usage

```
CE.ZINB.Init(data, init.locs, eps = 0.01, rho = 0.05, M = 200, h = 5, a = 0.8, b = 0.8, distyp = 1, penalty = "BIC", var.init = 1e+05, parallel = FALSE)
```

data	data to be analysed. A single column array or a dataframe.
init.locs	Initial break-point locations.
eps	the cut-off value for the stopping criterion in the CE method. Default value is $0.01$ .
rho	the fraction which is used to obtain the best performing set of sample solutions (i.e., elite sample). Default value is $0.05$ .
М	sample size to be used in simulating the locations of break-points. Default value is 200.
h	minimum aberration width. Default is 5.
a	a smoothing parameter value. It is used in the four parameter beta distribution to smooth both shape parameters. When simulating from the truncated normal distribution, this value is used to smooth the estimates of the mean values. Default is 0.8.

CE.ZINB.Init

b a smoothing parameter value. It is used in the truncated normal distribution to

smooth the estimates of the standard deviation. Default is 0.8.

distribution to simulate break-point locations. Options: 1 = four parameter beta

distribution, 2 = truncated normal distribution. Default is 1.

penalty User can select either BIC or AIC to obtain the number of break-points. Options:

"BIC", "AIC". Default is "BIC".

var.init Initial variance value to facilitate the search process. Default is 100000.

parallel A logical argument specifying if parallel computation should be carried-out

(TRUE) or not (FALSE). By default it is set as 'FALSE'. In WINDOWS OS systems "snow" functionalities are used, whereas in Unix/Linux/MAC OSX "multicore" functionalities are used to carryout parallel computations with the

maximum number of cores available.

#### **Details**

distyp

Zero-inflated negative binomial (ZINB) distribution is used to model the discrete (count) data. ZINB model is preferred over the NB model when both excess zero values and over-dispersion observed in the count data. A performance function score (BIC) is calculated for each of the solutions generated by the statistical distribution (four parameter beta distribution or truncated normal distribution), which is used to simulate break-points when the initial locations are provided. Finally, a list containing a vector of break-point locations, number of break-points, BIC/AIC values and log-likelihood value is returned in the console.

#### Value

A list is returned with following items:

No.BPs The number of break-points

BP.Loc A vector of break-point locations

BIC/AIC BIC/AIC value

11 Loglikelihood of the optimal solution

ch1.GM03563 23

ch1.GM03563

Fibroblast cell line (GM03563) data

## **Description**

Chromosome 1 of cell line GM03563

## Usage

```
data("ch1.GM03563")
```

#### **Format**

A single column data frame with 135 observations corresponds to chromosome 1 of cell line GM03563.

log2ratio normalized average of the log base 2 test over reference ratio data

#### **Details**

This data set is extracted from a single experiments on 15 fibroblast cell lines with each array containing over 2000 (mapped) BACs spotted in triplicate discussed in Snijders et al.(2001). Data corresponds to the chromosome 1 of cell line GM03563.

## End(Not run)</pre>
```

24 profilePlot

profilePlot

Mean profile plot

## **Description**

Plotting function to obtain mean profile plot of the testing dataset based on the estimates of the break-points. An R object created from the CE.Normal, CE.NB ot CE.ZINB is required. User can alter the axis names.

## Usage

```
profilePlot(obj, data, x.label = "Data Sequence", y.label = "Value")
```

## **Arguments**

obj R object created from CE.Normal, CE.NB or CE.ZINB.
data data to be analysed. A single column array or a dataframe.

x.label x axis label. Default is "Data Sequence".

y.label y axis label. Default is "Value".
