Package ‘polmineR’

September 22, 2020

Type Package
Title Verbs and Nouns for Corpus Analysis
Version 0.8.5
Date 2020-09-22
Depends R (>= 3.5.0)
Imports methods, data.table (>= 1.12.2), slam, Matrix, tm, DT, xml2,
       stringi, utils, jsonlite, parallel, pbapply, ReppCWB (>=
       0.2.2), magrittr, knitr
Suggests markdown, rmarkdown, htmltools (>= 0.4.0), highlight,
       sendmailR, shiny, shinythemes, miniUI, rhandsontable, testthat,
       tidytext, covr, igraph, NLP, httr, protolite, curl
VignetteBuilder knitr
LazyData yes
Description Package for corpus analysis using the Corpus Workbench
       ('CWB', <http://cwb.sourceforge.net/>) as an efficient back end for indexing
       and querying large corpora. The package offers functionality to flexibly create
       subcorpora and to carry out basic statistical operations (count, co-occurrences
       etc.). The original full text of documents can be reconstructed and inspected at
       any time. Beyond that, the package is intended to serve as an interface to
packages implementing advanced statistical procedures. Respective data structures
       (document-term matrices, term-co-occurrence matrices etc.) can be created based
       on the indexed corpora.

Description
A library for corpus analysis using the Corpus Workbench (CWB) as an efficient back end for indexing and querying large corpora.

Usage
polmineR()

Details
The package offers functionality to flexibly create partitions and to carry out basic statistical operations (count, co-occurrences etc.). The original full text of documents can be reconstructed and inspected at any time. Beyond that, the package is intended to serve as an interface to packages implementing advanced statistical procedures. Respective data structures (document term matrices, term co-occurrence matrices etc.) can be created based on the indexed corpora.

A session registry directory (see registry()) combines the registry files for corpora that may reside in anywhere on the system. Upon loading polmineR, the files in the registry directory defined by the environment variable CORPUS_REGISTRY are copied to the session registry directory. To see whether the environment variable CORPUS_REGISTRY is set, use the ‘Sys.getenv()’-function. Corpora wrapped in R data packages can be activated using the function use().

The package includes a draft shiny app that can be called using polmineR().

Package options
- **polmineR.p_attribute**: The default attribute
- **polmineR.left**: Default value for left context.
- **polmineR.lineview**: A logical value, whether ...
- **polmineR.pagelength**: 10L
- **polmineR.meta**:
- **polmineR.mc**:
- **polmineR.cores**:
- **polmineR.browse**:
- **polmineR.buttons**:
- **polmineR.specialChars**:
- **polmineR.cutoff**: 

polmineR-package
polmineR-package

- **polmineR.corpus_registry**: The system corpus registry directory defined by the environment variable CORPUS_REGISTRY before the polmineR package has been loaded. The polmineR package uses a temporary registry directory to be able to use corpora stored at multiple locations in one session. The path to the system corpus registry directory captures this setting to keep it available if necessary.

- **polmineR.shiny**: A logical value, whether polmineR is used in the context of a shiny app. Used to control the appearance of progress bars depending on whether shiny app is running, or not.

- **polmineR.warn.size**: When generating HTML table widgets (e.g. when preparing kwic output to be displayed in RStudio's View pane), the function DT::datatable() that is used internally will issue a warning by default if the object size of the table is greater than 1500000. The warning addresses a client-server scenario that is not applicable in the context of a local RStudio session, so you may want to turn it off. Internally, the warning can be suppressed by setting the option DT.warn.size to FALSE. The polmineR option polmineR.warn.size is processed by functions calling DT::datatable() to set and reset the value of DT.warn.size. Please note: The formulation of the warning does not match the scenario of a local RStudio session, but it may still be useful to get a warning when tables are large and slow to process. Therefore, the default value of the setting is FALSE.

Examples

```r
use("polmineR") # activate demo corpora included in the package

# The package includes two sample corpora
corpus("REUTERS") %>% show_info()
corpus("GERMAPARLMINI") %>% show_info()

# Core methods applied to corpus
C <- count("REUTERS", query = "oil")
C <- count("REUTERS", query = c("oil", "barrel"))
C <- count("REUTERS", query = "Saudi Arab.*", breakdown = TRUE, cqp = TRUE)
D <- dispersion("REUTERS", query = "oil", s_attribute = "id")
K <- kwic("REUTERS", query = "oil")
CO <- cooccurrences("REUTERS", query = "oil")

# Core methods applied to partition
kuwait <- partition("REUTERS", places = "kuwait", regex = TRUE)
C <- count(kuwait, query = "oil")
```
D <- dispersion(kuwait, query = "oil", s_attribute = "id")
K <- kwic(kuwait, query = "oil", meta = "id")
CO <- cooccurrences(kuwait, query = "oil")

# Go back to full text
p <- partition("REUTERS", id = 127)
if (interactive()) read(p)

h <- html(p)
h_highlighted <- highlight(h, highlight = list(yellow = "oil"))
if (interactive()) h_highlighted

# Generate term document matrix

pb <- partition_bundle("REUTERS", s_attribute = "id")

p <- partition("REUTERS", id = 127)

h <- html(p)
h_highlighted <- highlight(h, highlight = list(yellow = "oil"))
if (interactive()) h_highlighted

# Generate term document matrix

pb <- partition_bundle("REUTERS", s_attribute = "id")

cnt <- count(pb, p_attribute = "word")
tdm <- as.TermDocumentMatrix(cnt, col = "count")

---

**Annotations**

**Annotation functionality**

**Description**

Objects that contain analytical results (kwic objects, objects inheriting from the textstat class) can be annotated by creating an annotation layer using the annotations-method. The augmented object can be annotated using a shiny gadget by invoking the edit-method on it. Note that operations are deliberately in-place, to prevent an unwanted loss of work.

**Usage**

annotations(x, ...)

## S4 method for signature 'kwic'
annotations(x, i, j, value)

## S4 method for signature 'textstat'
annotations(x, i, j, value)

annotations(x) <- value

## S4 replacement method for signature 'kwic,list'
annotations(x) <- value

## S4 replacement method for signature 'textstat,list'
annotations(x) <- value

## S4 method for signature 'textstat'
edit(name, viewer = shiny::paneViewer(minHeight = 550), ...)
Annotations

Arguments

- **x**: An object to be annotated, a kwic class object, or an object inheriting from the textstat class.
- **...**: Passed into rhandsontable::rhandsontable, can be used for settings such as height etc.
- **i**: The row number (single integer value) of the data.table where a new value shall be assigned.
- **j**: The column number (single integer value) of the data.table where a new value shall be assigned.
- **value**: A value to assign.
- **name**: An S4 object to be annotated.
- **viewer**: The viewer to use, see viewer.

Details

The edit-method is designed to be used in a RStudio session. It generates a shiny gadget (see https://shiny.rstudio.com/articles/gadgets.html) shown in the viewer pane of RStudio.

The edit-method returns the modified input object. Note however that changes of annotations are deliberately in-place operations: The input object is changed even if you do not close the gadget "properly" by hitting the "Done" button and catch the modified object. That may be forgotten easily and would be painful after the work that may have been invested.

Consult the examples for the intended workflow.

Value

The modified input object is returned invisibly.

Examples

```r
use("polmineR")
a <- 2
# upon initializing a kwic object, there is a minimal labels object
# in the labels slot of the kwic object, which we can get using the
# annotations-method
o <- kwic("REUTERS", query = "oil")
annotations(o) # see the result (a data.table)

# assign new annotations as follows, using the reference semantics of the
# data.table you get by calling the labels-method on an object
annotations(o) <- list(name = "class", what = factor(x = "a", levels = c("a", "b", "c")))
annotations(o) <- list(name = "description", what = "")
annotations(o) # inspect the result

# assign values; note that is an in-place operation using the reference
# semantics of the data.table
# annotations(o, i = 77, j = 1, value = FALSE)
# annotations(o, i = 78, j = 1, value = FALSE)
annotations(o)
```
```r
## Not run:
edit(o)
annotations(o) # to see changes made

# maybe we want additional metadata
enrich(o, s_attributes = "places")
edit(o)
annotations(o)

# to get some extra context
o <- enrich(o, extra = 5L, table = TRUE)
edit(o)

# lineview may be better when you use a lot of extra context
options(polmineR.lineview = TRUE)
o <- kwic("REUTERS", "oil")
o <- enrich(o, extra = 20L)
edit(o)

x <- cooccurrences("REUTERS", query = "oil")
annotations(x) <- list(name = "keep", what = TRUE)
annotations(x) <- list(name = "category", what = factor("a", levels = letters[1:10]))
edit(x)

## End(Not run)
```

---

**as.markdown**  
*Get markdown-formatted full text of a partition.*

**Description**

The method is the worker behind the read-method, which will be called usually to reconstruct the full text of a partition and read it. The as.markdown-method can be customized for different classes inheriting from the partition-class.

**Usage**

```r
as.markdown(.Object, ...)
```

## S4 method for signature 'partition'

```r
as.markdown(.Object,
            meta = getOption("polmineR.meta"),
            template = get_template(.Object),
            cpos = TRUE,
            cutoff = NULL,
            verbose = FALSE,
            ...
```
## S4 method for signature 'subcorpus'
as.markdown(
  .Object,
  meta = getOption("polmineR.meta"),
  template = get_template(.Object),
  cpos = TRUE,
  cutoff = NULL,
  verbose = FALSE,
  ...
)

## S4 method for signature 'plpr_partition'
as.markdown(
  .Object,
  meta = NULL,
  template = get_template(.Object),
  cpos = FALSE,
  interjections = TRUE,
  cutoff = NULL,
  ...
)

## S4 method for signature 'plpr_subcorpus'
as.markdown(
  .Object,
  meta = NULL,
  template = get_template(.Object),
  cpos = FALSE,
  interjections = TRUE,
  cutoff = NULL,
  ...
)

### Arguments

- `.Object`: The object to be converted, a partition, or a class inheriting from partition, such as `plpr_partition`.
- `...`: further arguments
- `meta`: The metainformation (s-attributes) to be displayed.
- `template`: A template for formatting output.
- `cpos`: A logical value, whether to add cpos as ids in span elements.
- `cutoff`: The maximum number of tokens to reconstruct, to avoid that full text is excessively long.
- `verbose`: A logical value, whether to output messages.
- `interjections`: A logical value, whether to format interjections.
Examples

```r
use("polmineR")
P <- partition("REUTERS", places = "argentina")
as.markdown(P)
as.markdown(P, meta = c("id", "places"))
if (interactive()) read(P, meta = c("id", "places"))
```

---

**as.sparseMatrix**

*Type conversion - get sparseMatrix.*

---

**Description**

Turn objects into the sparseMatrix as defined in the Matrix package.

**Usage**

```r
as.sparseMatrix(x, ...)
```

## S4 method for signature 'simple_triplet_matrix'
```r
as.sparseMatrix(x, ...)
```

## S4 method for signature 'TermDocumentMatrix'
```r
as.sparseMatrix(x, ...)
```

## S4 method for signature 'bundle'
```r
as.sparseMatrix(x, col, ...)
```

**Arguments**

- `x` object to convert
- `...` Further arguments that are passed to a call to `sparseMatrix`. Can be used, for instance to set `giveCsparse` to `FALSE` to get a `dgTMatrix`, not a `dgCMatrix`.
- `col` column name to get values from (if `x` is a bundle)

---

**as.speeches**

*Split corpus or partition into speeches.*

---

**Description**

Split entire corpus or a partition into speeches. The heuristic is to split the corpus/partition into partitions on day-to-day basis first, using the s-attribute provided by `s_attribute_date`. These subcorpora are then split into speeches by speaker name, using s-attribute `s_attribute_name`. If there is a gap larger than the number of tokens supplied by argument `gap`, contributions of a speaker are assumed to be two separate speeches.
Usage

as.speeches(.Object, ...)

## S4 method for signature 'partition'
as.speeches(
  .Object,
  s_attribute_date = grep("date", s_attributes(.Object), value = TRUE),
  s_attribute_name = grep("name", s_attributes(.Object), value = TRUE),
  gap = 500,
  mc = FALSE,
  verbose = TRUE,
  progress = TRUE
)

## S4 method for signature 'subcorpus'
as.speeches(
  .Object,
  s_attribute_date = grep("date", s_attributes(.Object), value = TRUE),
  s_attribute_name = grep("name", s_attributes(.Object), value = TRUE),
  gap = 500,
  mc = FALSE,
  verbose = TRUE,
  progress = TRUE
)

## S4 method for signature 'corpus'
as.speeches(
  .Object,
  s_attribute_date = grep("date", s_attributes(.Object), value = TRUE),
  s_attribute_name = grep("name", s_attributes(.Object), value = TRUE),
  gap = 500,
  mc = FALSE,
  verbose = TRUE,
  progress = TRUE
)

## S4 method for signature 'character'
as.speeches(
  .Object,
  s_attribute_date = grep("date", s_attributes(.Object), value = TRUE),
  s_attribute_name = grep("name", s_attributes(.Object), value = TRUE),
  gap = 500,
  mc = FALSE,
  verbose = TRUE,
  progress = TRUE
)
Arguments

/Object A partition, or length-one character vector indicating a CWB corpus.

... Further arguments.

/s_attribute_date A length-one character vector, the s-attribute that provides the dates of sessions.

/s_attribute_name A length-one character vector, the s-attribute that provides the names of speakers.

gap An integer value, the number of tokens between strucs assumed to make the difference whether a speech has been interrupted (by an interjection or question), or whether to assume separate speeches.

mc Whether to use multicore, defaults to FALSE. If progress is TRUE, argument mc is passed into pblapply as argument cl. If progress is FALSE, mc is passed into mclapply as argument mc.cores.

verbose A logical value, defaults to TRUE.

progress A logical value, whether to show progress bar.

Value

A partition bundle, the names of the objects in the bundle are the speaker name, the date of the speech and an index for the number of the speech on a given day, concatenated by underscores.

Examples

use("polmineR")
speeches <- as.speeches(
  "GERMAPARLMINI",
  s_attribute_date = "date", s_attribute_name = "speaker"
)
speeches_count <- count(speeches, p_attribute = "word")
tdm <- as.TermDocumentMatrix(speeches_count, col = "count")

bt <- partition("GERMAPARLMINI", date = "2009-10-27")
speeches <- as.speeches(bt, s_attribute_name = "speaker")
summary(speeches)
sp <- as.speeches(.Object = corpus("GERMAPARLMINI"), s_attribute_name = "speaker")

Description

Methods to generate the classes TermDocumentMatrix or DocumentTermMatrix as defined in the tm package. There are many text mining applications for document-term matrices. A DocumentTermMatrix is required as input by the topicmodels package, for instance.
Usage

as.TermDocumentMatrix(x, ...)

as.DocumentTermMatrix(x, ...)

## S4 method for signature 'character'
as.TermDocumentMatrix(x, p_attribute, s_attribute, verbose = TRUE, ...)

## S4 method for signature 'character'
as.DocumentTermMatrix(x, p_attribute, s_attribute, verbose = TRUE, ...)

## S4 method for signature 'bundle'
as.TermDocumentMatrix(x, col, p_attribute = NULL, verbose = TRUE, ...)

## S4 method for signature 'bundle'
as.DocumentTermMatrix(x, col = NULL, p_attribute = NULL, verbose = TRUE, ...)

## S4 method for signature 'partition_bundle'
as.DocumentTermMatrix(x, p_attribute = NULL, col = NULL, verbose = TRUE, ...)

## S4 method for signature 'partition_bundle'
as.TermDocumentMatrix(x, p_attribute = NULL, col = NULL, verbose = TRUE, ...)

## S4 method for signature 'subcorpus_bundle'
as.DocumentTermMatrix(x, p_attribute = NULL, verbose = TRUE, ...)

## S4 method for signature 'subcorpus_bundle'
as.TermDocumentMatrix(x, p_attribute = NULL, verbose = TRUE, ...)

## S4 method for signature 'context'
as.DocumentTermMatrix(x, p_attribute, verbose = TRUE, ...)

## S4 method for signature 'context'
as.TermDocumentMatrix(x, p_attribute, verbose = TRUE, ...)

Arguments

x A character vector indicating a corpus, or an object of class bundle, or inheriting from class bundle (e.g. partition_bundle).

... Definitions of s-attribute used for subsetting the corpus, compare partition-method.

p_attribute A p-attribute counting is be based on.

s_attribute An s-attribute that defines content of columns, or rows.

verbose A logical value, whether to output progress messages.
col

The column of data.table in slot stat (if x is a bundle) to use of assembling the matrix.

Details

If x refers to a corpus (i.e. is a length 1 character vector), a TermDocumentMatrix, or DocumentTermMatrix will be generated for subsets of the corpus based on the s_attribute provided. Counts are performed for the p_attribute. Further parameters provided (passed in as ... are interpreted as s-attributes that define a subset of the corpus for splitting it according to s_attribute. If struc values for s_attribute are not unique, the necessary aggregation is performed, slowing things somewhat down.

If x is a bundle or a class inheriting from it, the counts or whatever measure is present in the stat slots (in the column indicated by col) will be turned into the values of the sparse matrix that is generated. A special case is the generation of the sparse matrix based on a partition_bundle that does not yet include counts. In this case, a p_attribute needs to be provided. Then counting will be performed, too.

If x is a partition_bundle, and argument col is not NULL, as TermDocumentMatrix is generated based on the column indicated by col of the data.table with counts in the stat slots of the objects in the bundle. If col is NULL, the p-attribute indicated by p_attribute is decoded, and a count is performed to obtain the values of the resulting TermDocumentMatrix. The same procedure applies to get a DocumentTermMatrix.

If x is a subcorpus_bundle, the p-attribute provided by argument p_attribute is decoded, and a count is performed to obtain the resulting TermDocumentMatrix or DocumentTermMatrix.

Value

A TermDocumentMatrix, or a DocumentTermMatrix object. These classes are defined in the tm package, and inherit from the simple_triplet_matrix-class defined in the slam-package.

Author(s)

Andreas Blaette

Examples

use("polmineR")

# enriching partition_bundle explicitly
tdm <- partition("GERMAPARLMINI", date = ".*", regex = TRUE) %>%
  partition_bundle(s_attribute = "date") %>%
  enrich(p_attribute = "word") %>%
  as.TermDocumentMatrix(col = "count")

# leave the counting to the as.TermDocumentMatrix-method
tdm <- partition_bundle("GERMAPARLMINI", s_attribute = "date") %>%
  as.TermDocumentMatrix(p_attribute = "word", verbose = FALSE)

# obtain TermDocumentMatrix directly (fastest option)
tdm <- as.TermDocumentMatrix("GERMAPARLMINI", p_attribute = "word", s_attribute = "date")
as.VCorpus

```r
dtm <- corpus("REUTERS") %>%
split(s_attribute = "id") %>%
as.TermDocumentMatrix(p_attribute = "word")
```

---

**as.VCorpus**

**Get VCorpus.**

**Description**

Retrieve full text for the subcorpora or partition objects in a subcorpus_bundle or partition_bundle and generate a VCorpus-class object from the tm-package.

**Usage**

```
## S4 method for signature 'partition_bundle'
as.VCorpus(x)
```

**Arguments**

- `x` A partition_bundle object.

**Details**

The VCorpus class of the tm-package offers an interface to access the functionality of the tm-package. Note however that generating a VCorpus to get a DocumentTermMatrix or a TermDocumentMatrix is a highly inefficient detour. Applying the as.DocumentTermMatrix or as.TermDocumentMatrix methods on a partition_bundle is the recommended approach.

If the tm-package has been loaded, the as.VCorpus-method included in the polmineR-package may become inaccessible. To deal with this (propable) scenario, it is possible to use a coerce-method (as(YOUROBJECT,"VCorpus")), see examples.

**Examples**

```
pb <- partition("GERMAPARLMINI", date = "2009-11-10") %>%
  partition_bundle(s_attribute = "speaker")

vc <- as.VCorpus(pb) # works only, if tm-package has not yet been loaded
vc <- as(pb, "VCorpus") # will work if tm-package has been loaded, too
vc <- corpus("REUTERS") %>%
  split(s_attribute = "id") %>%
  as("VCorpus")
```
**blapply**

*apply a function over a list or bundle*

**Description**

Very similar to `lapply`, but applicable to bundle-objects, in particular. The purpose of the method is to supply a uniform and convenient parallel backend for the polmineR package. In particular, progress bars are supported (the naming of the method is derived from bla bla).

**Usage**

```r
blapply(x, ...)  
```

## S4 method for signature 'list'

```r
blapply(x, f, mc = TRUE, progress = TRUE, verbose = FALSE, ...)
```

## S4 method for signature 'vector'

```r
blapply(x, f, mc = FALSE, progress = TRUE, verbose = FALSE, ...)
```

## S4 method for signature 'bundle'

```r
blapply(x, f, mc = FALSE, progress = TRUE, verbose = FALSE, ...)
```

**Arguments**

- `x`: a list or a bundle object
- `f`: a function that can be applied to each object contained in the bundle, note that it should swallow the parameters `mc`, `verbose` and `progress` (use `...` to catch these params)
- `mc`: logical, whether to use multicore - if TRUE, the number of cores will be taken from the polmineR-options
- `progress`: logical, whether to display progress bar
- `verbose`: logical, whether to print intermediate messages

**Examples**

```r
use("polmineR")
between <- partition("GERMAPARLMINI", date = ".x", regex=TRUE)
speeches <- as.speeches(bt, s_attribute_date = "date", s_attribute_name = "speaker")
foo <- blapply(speeches, function(x, ...) slot(x, "cpos"))
```
bundle-class

Bundle Class

Description

A bundle is used to combine several objects (partition, context, features, cooccurrences objects) into one S4 class object. Typically, a class inheriting from the bundle superclass will be used. When working with a context_bundle, a features_bundle, a cooccurrences_bundle, or a context_bundle, a similar set of standard methods is available to perform transformations.

Usage

```r
## S4 replacement method for signature 'bundle'
name(x) <- value

## S4 method for signature 'bundle'
length(x)

## S4 method for signature 'bundle'
names(x)

## S4 replacement method for signature 'bundle,vector'
names(x) <- value

## S4 method for signature 'bundle'
unique(x)

## S4 method for signature 'bundle,bundle'
e1 + e2

## S4 method for signature 'bundle,textstat'
e1 + e2

## S4 method for signature 'bundle'
x[[i]]

## S4 replacement method for signature 'bundle'
x[[i]] <- value

## S4 method for signature 'bundle'
x$name

## S4 replacement method for signature 'bundle'
x$name <- value

## S4 method for signature 'bundle'
sample(x, size)
```
## S4 method for signature 'list'
as.bundle(object, ...)

## S4 method for signature 'textstat'
as.bundle(object)

## S3 method for class 'bundle'
as.data.table(x, keep.rownames, col, ...)

## S4 method for signature 'bundle'
as.matrix(x, col)

## S4 method for signature 'bundle'
subset(x, ...)

## S4 method for signature 'bundle'
as.list(x)

## S3 method for class 'bundle'
as.list(x, ...)

## S4 method for signature 'bundle'
get_corpus(x)

### Arguments

- **x**
  - a bundle object

- **value**
  - character string with a name to be assigned

- **e1**
  - object 1

- **e2**
  - object 2

- **i**
  - An integer value to index a bundle object.

- **name**
  - The name of an object in the bundle object.

- **size**
  - number of items to choose to generate a sample

- **object**
  - A bundle object.

- **...**
  - Further parameters

- **keep.rownames**
  - Required argument to safeguard consistency with S3 method definition in the data.table package. Unused in this context.

- **col**
  - columns of the data.table to use to generate an object.

### Slots

- **corpus**
  - The CWB corpus the objects in the bundle are based on, a length 1 character vector.

- **objects**
  - An object of class list.

- **p_attribute**
  - Object of class character.

- **encoding**
  - The encoding of the corpus.
Author(s)
Andreas Blaette

Examples

```
parties <- s_attributes("GERMAPARLMINI", "party")
parties <- parties[-which(parties == "NA")]
party_bundle <- partition_bundle("GERMAPARLMINI", s_attribute = "party")
length(party_bundle)
names(party_bundle)
get_corpus(party_bundle)
party_bundle <- enrich(party_bundle, p_attribute = "word")
summary(party_bundle)
parties_big <- party_bundle[[c("CDU_CSU", "SPD")]]
summary(parties_big)
p <- partition("GERMAPARLMINI", date = "2009-11-11")
pb <- partition_bundle(p, s_attribute = "party")
names(pb)
pb["NA"] <- NULL
names(pb)
pb <- partition_bundle("GERMAPARLMINI", s_attribute = "party")
pb$"SPD" # access partition names "SPD" in partition_bundle pb
pb$"NA" <- NULL # quotation needed if name is "NA"
use("polmineR")
coocs <- cooccurrences(pb, query = "oil", cqp = FALSE)
dt <- as.data.table(coocs, col = "ll")
m <- as.matrix(dt[, 2:ncol(dt)], rownames = dt["token"]]
```

---

**chisquare**

Perform chisquare-test.

**Description**

Perform Chisquare-Test based on a table with counts

**Usage**

```
chisquare(.Object)
```

## S4 method for signature 'features'

```
chisquare(.Object)
```

## S4 method for signature 'context'

```
chisquare(.Object)
```

## S4 method for signature 'cooccurrences'

```
chisquare(.Object)
```
Arguments

_Object_ A features object, or an object inheriting from it (context, cooccurrences).

Details

The basis for computing for the chi square test is a contingency table of observationes, which is prepared for every single token in the corpus. It reports counts for a token to inspect and all other tokens in a corpus of interest (coi) and a reference corpus (ref):

<table>
<thead>
<tr>
<th></th>
<th>coi</th>
<th>ref</th>
<th>TOTAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>count token</td>
<td>$o_{11}$</td>
<td>$o_{12}$</td>
<td>$r_1$</td>
</tr>
<tr>
<td>other tokens</td>
<td>$o_{21}$</td>
<td>$o_{22}$</td>
<td>$r_2$</td>
</tr>
<tr>
<td>TOTAL</td>
<td>$c_1$</td>
<td>$c_2$</td>
<td>$N$</td>
</tr>
</tbody>
</table>

Based on the contingency table, expected values are calculated for each cell, as the product of the column and margin sums, divided by the overall number of tokens (see example). The standard formula for calculating the chi-square test is computed as follows.

$$X^2 = \sum \frac{(O_{ij} - E_{ij})^2}{O_{ij}}$$

Results from the chisquare test are only robust for at least 5 observed counts in the corpus of interest. Usually, results need to be filtered accordingly (see examples).

Value

Same class as input object, with enriched table in the stat-slot.

)

## S4 method for signature 'partition_bundle'
context(.Object, query, p_attribute, verbose = TRUE, ...)

## S4 method for signature 'cooccurrences'
context(.Object, query, check = TRUE, complete = FALSE)

Arguments

.Object a partition or a partition_bundle object
...
query A query, which may by a character vector or a CQP query.
cqp defaults to is.cqp-function, or provide TRUE/FALSE
check A logical value, whether to check validity of CQP query using check_cqp_query.
left Number of tokens to the left of the query match.
right Number of tokens to the right of the query match.
p_attribute The p-attribute of the query.
boundary If provided, a length-one character vector specifying a s-attribute. It will be checked that corpus positions do not extend beyond the region defined by the s-attribute.
stoplist Exclude match for query if stopword(s) is/are are present in context. See positivelist for further explanation.
positivelist character vector or numeric/integer vector: include a query hit only if token in positivelist is present. If positivelist is a character vector, it may include regular expressions (see parameter regex)
regex logical, defaults to FALSE - whether stoplist and/or positivelist are regular expressions
count logical
mc whether to use multicore; if NULL (default), the function will get the value from the options
verbose report progress, defaults to TRUE
progress logical, whether to show progress bar
corpus A length-one character vector stating the corpus ID of a CWB corpus.
complete enhance completely
Details

For formulating the query, CPQ syntax may be used (see examples). Statistical tests available are log-likelihood, t-test, pmi.

If .Object is a matrix, the context-method will unfold the matrix (interpreted as regions defining left and right corpus positions) and return an elementary ... object.

Value

depending on whether a partition or a partition_bundle serves as input, the return will be a context object, or a context_bundle object

Author(s)

Andreas Blaette

Examples

use("polmineR")
p <- partition("GERMAPARLMINI", interjection = "speech")
y <- context(p, query = "Integration", p_attribute = "word")
y <- context(p, query = "Integration", p_attribute = "word", positivelist = "Bildung")
y <- context(  
p, query = "Integration", p_attribute = "word",  
  positivelist = c("[aA]rbeit.*", "Ausbildung"), regex = TRUE  
)

context-class

Context class.

Description

Class to organize information of context analysis.

Usage

## S4 method for signature 'context'
length(x)

## S4 method for signature 'context'
p_attributes(.Object)

## S4 method for signature 'context'
count(.Object)

## S4 method for signature 'context'
sample(x, size)
## S4 method for signature 'context'
enrich(
  .Object,
  s_attribute = NULL,
  p_attribute = NULL,
  decode = FALSE,
  verbose = TRUE,
  ...
)

## S4 method for signature 'context'
as.regions(x, node = TRUE)

## S4 method for signature 'context'
trim(
  object,
  s_attribute = NULL,
  positivelist = NULL,
  p_attribute = p_attributes(object),
  regex = FALSE,
  stoplist = NULL,
  verbose = TRUE,
  progress = TRUE,
  ...
)

### Arguments

- **x**
  - a context object

- **.Object**
  - object

- **size**
  - integer indicating sample size

- **s_attribute**
  - s-attribute(s) to add to data.table in cpos-slot

- **p_attribute**
  - p-attribute(s) to add to data.table in cpos-slot

- **decode**
  - logical, whether to convert integer ids to expressive strings

- **verbose**
  - logical, whether to be talkative

- **node**
  - A logical value, whether to include the node (i.e. query matches) in the region matrix generated when creating a partition from a context-object.

- **object**
  - a context object

- **positivelist**
  - tokens that are required to be present to keep a match

- **regex**
  - logical, whether positivelist / stoplist is interpreted as regular expressions

- **stoplist**
  - tokens that are used to exclude a match

- **progress**
  - logical, whether to show progress bar
Details

Objects of the class context include a data.table in the slot cpos. The data.table will at least include the columns "match_id", "cpos" and "position".

The length-method will return the number of hits that were achieved.

The enrich-method can be used to add additional information to the data.table in the "cpos"-slot of a context-object.

Slots

query  The query examined (character).
count  An integer value, the number of hits for the query.
partition The partition the context object is based on.
size_partition The size of the partition, a length-one integer vector.
left  A length-one integer value, the number of tokens to the left of the query match.
right An integer value, the number of tokens to the right of the query match.
size A length-one integer value, the number of tokens covered by the context-object, i.e. the number of tokens in the right and left context of the node as well as query matches.
size_match A length-one integer value, the number of tokens matches by the query. Identical with the value in slot count if the query is not a CQP query.
size_coii A length-one integer value, the number of tokens in the right and left context of the node (excluding query matches).
size_ref A length-one integer value, the number of tokens in the partition, without tokens matched and the tokens in the left and right context.
boundary An s-attribute (character).
p_attribute The p-attribute of the query (character).
corpus The CWB corpus used (character).
stat A data.table, the statistics of the analysis.
encoding Object of class character, encoding of the corpus.
cpos A data.table, with the columns match_id, cpos, position, word_id.
method A character-vector, statistical test used.
call Object of class character, call that generated the object.

context_bundle-class  S4 context_bundle class

Description

class to organize information of multiple context analyses

Slots

objects  Object of class "list" a list of context objects
Methods

- **show** output of core information
- **summary** core statistical information
  - [ specific cooccurrences
  - [[ specific cooccurrences

---

**cooccurrences**

Get cooccurrence statistics.

Description

Get cooccurrence statistics.

Usage

```r
cooccurrences(.Object, ...)
```

## S4 method for signature 'corpus'
```r
coop = is.cqp,
query,
query = getOption("polmineR.p_attribute"),
boundary = NULL,
left = getOption("polmineR.left"),
right = getOption("polmineR.right"),
stoplist = NULL,
positivelist = NULL,
regex = FALSE,
keep = NULL,
cpos = NULL,
method = "ll",
mc = getOption("polmineR.mc"),
verbose = FALSE,
progress = FALSE,
...)
```

## S4 method for signature 'character'
```r
coop = is.cqp,
query,
query = getOption("polmineR.p_attribute"),
boundary = NULL,
left = getOption("polmineR.left"),
...)
```
right = getOption("polmineR.right"),
stoplist = NULL,
positivelist = NULL,
regex = FALSE,
keep = NULL,
cpos = NULL,
method = "ll",
mc = getOption("polmineR.mc"),
verbose = FALSE,
progress = FALSE,
...}
}
## S4 method for signature 'slice'
cooccurrences(
 .Object,
 query,
 cqp = is.cqp,
 left = getOption("polmineR.left"),
 right = getOption("polmineR.right"),
 p_attribute = getOption("polmineR.p_attribute"),
 boundary = NULL,
 stoplist = NULL,
 positivelist = NULL,
 keep = NULL,
 method = "ll",
 mc = FALSE,
 progress = TRUE,
 verbose = FALSE,
...}
## S4 method for signature 'partition'
cooccurrences(
 .Object,
 query,
 cqp = is.cqp,
 left = getOption("polmineR.left"),
 right = getOption("polmineR.right"),
 p_attribute = getOption("polmineR.p_attribute"),
 boundary = NULL,
 stoplist = NULL,
 positivelist = NULL,
 keep = NULL,
 method = "ll",
 mc = FALSE,
 progress = TRUE,
 verbose = FALSE,
 Arguments

/Object A partition object, or a character vector with a CWB corpus.

/query Further parameters that will be passed into bigmatrix (applies only of big = TRUE).

cqp A query, either a character vector to match a token, or a CQP query.

cqp Defaults to is.cqp-function, or provide TRUE/FALSE; relevant only if query is not NULL.

/p_attribute The p-attribute of the tokens/the query.

/boundary If provided, it will be checked that the corpus positions of windows do not extend beyond the left and right boundaries of the region defined by the s-attribute.
cooccurrences

where the match occurs.

left  Number of tokens to the left of the query match.
right Number of tokens to the right of the query match.
stoplist Exclude a query hit from analysis if stopword(s) is/are in context (relevant only if query is not NULL).
positivelist Character vector or numeric vector: include a query hit only if token in positivelist is present. If positivelist is a character vector, it is assumed to provide regex expressions (incredibly long if the list is long) (relevant only if query is not NULL).
regex A logical value, whether stoplist/positivelist are interpreted as regular expressions.
keep list with tokens to keep
cpos integer vector with corpus positions, defaults to NULL - then the corpus positions for the whole corpus will be used
method The statistical test(s) to use (defaults to "ll").
mc whether to use multicore
verbose A logical value, whether to be verbose.
progress A logical value, whether to output progress bar.

Value

a cooccurrences-class object

Author(s)

Andreas Blaette

See Also

See the documentation for the 11-method for an explanation of the computation of the log-likelihood statistic.

Examples

use("polmineR")
merkel <- partition("GERMAPARLMINI", interjection = "speech", speaker = ".*Merkel", regex = TRUE)
merkel <- enrich(merkel, p_attribute = "word")
cooc <- cooccurrences(merkel, query = "Deutschland")

# use subset-method to filter results
Cooccurrences, corpus-method

Get all cooccurrences in corpus/partition.

Description

Obtain all cooccurrences in a corpus, or a partition. The result is a Cooccurrences-class object which includes a data.table with counts of cooccurrences. See the documentation entry for the Cooccurrences-class for methods to process Cooccurrences-class objects.

Usage

## S4 method for signature 'corpus'
Cooccurrences(
  .Object,
  p_attribute,
  left,
  right,
  stoplist = NULL,
  mc =getOption("polmineR.mc"),
  verbose = FALSE,
  progress = FALSE,
  ...
Cooccurrences.corpus-method

## S4 method for signature 'character'
Cooccurrences(
  .Object,
  p_attribute,
  left,
  right,
  stoplist = NULL,
  mc = getOption("polmineR.mc"),
  verbose = FALSE,
  progress = FALSE
)

## S4 method for signature 'slice'
Cooccurrences(
  .Object,
  p_attribute,
  left,
  right,
  stoplist = NULL,
  mc = getOption("polmineR.mc"),
  verbose = FALSE,
  progress = FALSE
)

## S4 method for signature 'partition'
Cooccurrences(
  .Object,
  p_attribute,
  left,
  right,
  stoplist = NULL,
  mc = getOption("polmineR.mc"),
  verbose = FALSE,
  progress = FALSE
)

## S4 method for signature 'subcorpus'
Cooccurrences(
  .Object,
  p_attribute,
  left,
  right,
  stoplist = NULL,
  mc = getOption("polmineR.mc"),
  verbose = FALSE,
  progress = FALSE
)
Arguments

- **.Object**: A length-one character vector indicating a corpus, or a partition object.
- **p_attribute**: Positional attributes to evaluate.
- **left**: A scalar integer value, size of left context.
- **right**: A scalar integer value, size of right context.
- **stoplist**: Tokens to exclude from the analysis.
- **mc**: Logical value, whether to use multiple cores.
- **verbose**: Logical value, whether to output messages.
- **progress**: Logical value, whether to display a progress bar.

Details

The implementation uses a data.table to store information and makes heavy use of the reference logic of the data.table package, to avoid copying potentially large objects, and to be parsimonious with limited memory. The behaviour resulting from in-place changes may be uncommon, see examples.

See Also

To learn about methods available for the object that is returned, see the documentation of the Cooccurrences-class. See the cooccurrences-method (starting with a lower case c) to get the cooccurrences for the match for a query, which may also be a CQP query.

Examples

```r
## Not run:
# In a first scenario, we get all cooccurrences for the REUTERS corpus,
# excluding stopwords

stopwords <- unname(unlist(noise(
  terms("REUTERS", p_attribute = "word"),
  stopwordsLanguage = "en"
))
)

r <- Cooccurrences(.Object = "REUTERS", p_attribute = "word",
  left = 5L, right = 5L, stoplist = stopwords)
ll(r) # note that the table in the stat slot is augmented in-place

decode(r) # in-place modification, again

r <- subset(r, ll > 11.83 & ab_count >= 5)

)
ll(merkel_cooc)
decode(merkel_cooc)

f <- features(merkel_cooc, protocol_cooc)
f <- subset(f, a_pos %in% c("NN", "ADJA"))
f <- subset(f, b_pos %in% c("NN", "ADJA"))
f <- subset(f, c(rep(TRUE, times = 50), rep(FALSE, times = nrow(f) - 50)))

merkel_min <- subset(merkel_cooc, by = f)

if (requireNamespace("igraph", quietly = TRUE)){
  g <- as_igraph(merkel_min, as.undirected = TRUE)
Description

The Cooccurrences-class stores the information for all cooccurrences in a corpus. As this data can be bulky, in-place modifications of the data.table in the stat-slot of a Cooccurrences-object are used wherever possible, to avoid copying potentially large objects whenever possible. The class inherits from the textstat-class, so that methods for textstat-objects are inherited (see examples).

Usage

```r
## S4 method for signature 'Cooccurrences'
as.simple_triplet_matrix(x)

## S4 method for signature 'Cooccurrences'
as.igraph(
  x,
  edge_attributes = c("ll", "ab_count", "rank_ll"),
  vertex_attributes = "count",
  as.undirected = TRUE,
  drop = getOption("polmineR.villainChars")
)

## S4 method for signature 'Cooccurrences'
subset(x, ..., by)

## S4 method for signature 'Cooccurrences'
decode(.Object)

## S4 method for signature 'Cooccurrences'
kwic(
  .Object,
  left = getOption("polmineR.left"),
  right = getOption("polmineR.right"),
  verbose = TRUE,
  progress = TRUE
)
```

```r
plot(g)
}

## End(Not run)
```
as.sparseMatrix(x, col = "ab_count", ...)

## S4 method for signature 'Cooccurrences'
enrich(.Object)

### Arguments

- **x**: A Cooccurrences class object.
- **edge_attributes**: Attributes from stat data.table in x to add to edges.
- **vertex_attributes**: Vertex attributes to add to nodes.
- **as.undirected**: Logical, whether to return directed or undirected graph.
- **drop**: A character vector indicating names of nodes to drop from igraph object that is prepared.
- **...**: Further arguments passed into a further call of subset.
- **by**: A features-class object.
- **.Object**: A Cooccurrences-class object.
- **left**: Number of tokens to the left of the node.
- **right**: Number of tokens to the right of the node.
- **verbose**: Logical.
- **progress**: Logical, whether to show progress bar.
- **col**: A column to extract.

### Details

The as.simple_triplet_matrix-method will transform a Cooccurrences object into a sparse matrix. For reasons of memory efficiency, decoding token ids is performed within the method at the as late as possible. It is NOT necessary that decoded tokens are present in the table in the Cooccurrences object.

The as_igraph-method can be used to turn an object of the Cooccurrences-class into an igraph-object.

The subset method, as a particular feature, allows a Coocccurrences-object to be subsetted by a features-Object resulting from a features extraction that compares two Cooccurrences objects.

For reasons of memory efficiency, the initial data.table in the slot stat of a Cooccurrences-object will identify tokens by an integer id, not by the string of the token. The decode()-method will replace these integer columns with human-readable character vectors. Due to the reference logic of the data.table object, this is an in-place operation, performed without copying the table.

The modified object is returned invisibly; usually it will not be necessary to catch the return value.

The kwic-method will add a column to the data.table in the stat-slot with the concordances that are behind a statistical finding, and to the data.table in the stat-slot of the partition in the slot partition. It is an in-place operation.

Returns a sparseMatrix based on the counts of term cooccurrences. At this stage, it is required that decoded tokens are present.
The enrich-method will add columns 'a_count' and 'b_count' to the data.table in the 'stat' slot of the Cooccurrences object. If the count for the subcorpus/partition from which the cooccurrences are derived is not yet present, the count is performed first.

**Slots**

- **left** Single integer value, number of tokens to the left of the node.
- **right** Single integer value, number of tokens to the right of the node.
- **p_attribute** A character vector, the p-attribute(s) the evaluation of the corpus is based on.
- **corpus** Length-one character vector, the CWB corpus used.
- **stat** A data.table with the statistical analysis of cooccurrences.
- **encoding** Length-one character vector, the encoding of the corpus.
- **partition** The partition that is the basis for computations.
- **window_sizes** A data.table linking the number of tokens in the context of a token identified by id.
- **minimized** Logical, whether the object has been minimized.

**See Also**

See the documentation of the Cooccurrences-method (including examples) for procedures to get and filter cooccurrence information. See the documentation for the textstat-class explaining which methods for this superclass of the Cooccurrences-class which are available.

**Examples**

```r
X <- Cooccurrences("REUTERS", p_attribute = "word", left = 2L, right = 2L)
m <- as.simple_triplet_matrix(X)
# Not run:
X <- Cooccurrences("REUTERS", p_attribute = "word", left = 5L, right = 5L)
decode(X)
sm <- as.sparseMatrix(X)
stm <- as.simple_triplet_matrix(X)
# End(Not run)
```

---

**Description**

S4 class to organize information of context analysis
Usage

```r
## S4 method for signature 'cooccurrences'
show(object)

## S4 method for signature 'cooccurrences_bundle'
as.data.frame(x)

## S4 method for signature 'cooccurrences'
format(x, digits = 2L)

## S4 method for signature 'cooccurrences'
view(.Object)

## S4 method for signature 'cooccurrences_resized'
view(.Object)
```

Arguments

- `object`: object to work with
- `x`: object to work with
- `digits`: Integer indicating the number of decimal places (round) or significant digits (signif) to be used.
- `.Object`: object to work with

Slots

- `call`: Object of class character the call that generated the object
- `partition`: Object of class character the partition the analysis is based on
- `size_partition`: Object of class integer the size of the partition
- `left`: Object of class integer number of tokens to the left.
- `right`: Object of class integer number of tokens to the right.
- `p_attribute`: Object of class character p-attribute of the query
- `corpus`: Object of class character the CWB corpus used
- `stat`: Object of class data.table statistics of the analysis
- `encoding`: Object of class character encoding of the corpus
- `method`: Object of class character statistical test(s) used
Corpus class initialization

Description

Corpora indexed using the Corpus Workbench (CWB) offer an efficient data structure for large, linguistically annotated corpora. The corpus-class keeps basic information on a CWB corpus. Corresponding to the name of the class, the corpus-method is the initializer for objects of the corpus class. A CWB corpus can also be hosted remotely on an OpenCPU server. The remote_corpus class (which inherits from the corpus class) will handle respective information. A (limited) set of polmineR functions and methods can be executed on the corpus on the remote machine from the local R session by calling them on the remote_corpus object. Calling the corpus-method without an argument will return a data.frame with basic information on the corpora that are available.

Usage

```r
## S4 method for signature 'character'
corpus(.Object, server = NULL, restricted)
## S4 method for signature 'missing'
corpus()
```

Arguments

- `.Object` The upper-case ID of a CWB corpus stated by a length-one character vector.
- `server` If NULL (default), the corpus is expected to be present locally. If provided, the name of an OpenCPU server (can be an IP address) that hosts a corpus, or several corpora. The corpus-method will then instantiate a remote_corpus object.
- `restricted` A logical value, whether access to a remote corpus is restricted (TRUE) or not (FALSE).

Details

Calling corpus() will return a data.frame listing the corpora available locally and described in the active registry directory, and some basic information on the corpora.

A corpus object is instantiated by passing a corpus ID as argument .Object. Following the conventions of the Corpus Workbench (CWB), Corpus IDs are written in upper case. If .Object includes lower case letters, the corpus object is instantiated nevertheless, but a warning is issued to prevent bad practice. If .Object is not a known corpus, the error message will include a suggestion if there is a potential candidate that can be identified by agrep.

A limited set of methods of the polmineR package is exposed to be executed on a remote OpenCPU server. As a matter of convenience, the whereabouts of an OpenCPU server hosting a CWB corpus can be stated in an environment variable "OPENCPU_SERVER". Environment variables for R sessions can be set easily in the .Renviron file. A convenient way to do this is to call usethis::edit_r_environ().
Slots

corpus  A length-one character vector, the upper-case ID of a CWB corpus.
data_dir  The directory where the files for the indexed corpus are.
type  The type of the corpus (e.g. "plpr" for a corpus of plenary protocols).
name  An additional name for the object that may be more telling than the corpus ID.
encoding  The encoding of the corpus, given as a length-one character vector.
size  Number of tokens (size) of the corpus, a length-one integer vector.
server  The URL (can be IP address) of the OpenCPU server. The slot is available only with the remote_corpus class inheriting from the corpus class.
user  If the corpus on the server requires authentication, the username.
password  If the corpus on the server requires authentication, the password.

See Also

Methods to extract basic information from a corpus object are covered by the corpus-methods documentation object. Use the s_attributes method to get information on structural attributes. Analytical methods available for corpus objects are size, count, dispersion, kwic, cooccurrences, as.TermDocumentMatrix.

Other classes to manage corpora: phrases, regions, subcorpus

Examples

use("polmineR")

# get corpora present locally
y <- corpus()

# initialize corpus object
r <- corpus("REUTERS")
r <- corpus("reuters") # will work, but will result in a warning

# apply core polmineR methods
a <- size(r)
b <- s_attributes(r)
c <- count(r, query = "oil")
d <- dispersion(r, query = "oil", s_attribute = "id")
e <- kwic(r, query = "oil")
f <- cooccurrences(r, query = "oil")

# used corpus initialization in a pipe
y <- corpus("REUTERS") %>% s_attributes()
y <- corpus("REUTERS") %>% count(query = "oil")

# working with a remote corpus
## Not run:
REUTERS <- corpus("REUTERS", server = Sys.getenv("OPENCPU_SERVER"))
count(REUTERS, query = "oil")
size(REUTERS)
kwic(REUTERS, query = "oil")

GERMAPARL <- corpus("GERMAPARL", server = Sys.getenv("OPENCPU_SERVER"))
s_attributes(GERMAPARL)
size(x = GERMAPARL)
count(GERMAPARL, query = "Integration")
kwic(GERMAPARL, query = "Islam")

p <- partition(GERMAPARL, year = 2000)
s_attributes(p, s_attribute = "year")
size(p)
kwic(p, query = "Islam", meta = "date")

GERMAPARL <- corpus("GERMAPARLMINI", server = Sys.getenv("OPENCPU_SERVER"))
s_attrs <- s_attributes(GERMAPARL, s_attribute = "date")
sc <- subset(GERMAPARL, date == "2009-11-10")

## End(Not run)

---

**corpus-methods**

**Corpus class methods**

**Description**

A set of generic methods is available to extract basic information from objects of the corpus class.

**Usage**

```r
## S4 method for signature 'corpus'
name(x)

## S4 method for signature 'corpus'
get_corpus(x)

## S4 method for signature 'corpus'
show(object)

## S4 method for signature 'corpus'
x$name

## S4 method for signature 'corpus'
get_info(x)

## S4 method for signature 'corpus'
show_info(x)
```
Arguments

- **x**: An object of class `corpus`, or inheriting from it.
- **object**: An object of class `corpus`, or inheriting from it.
- **name**: A (single) s-attribute.

Details

A corpus object can have a name, which can be retrieved using the `name`-method.

Use `get_corpus`-method to get the corpus ID from the slot `corpus` of the corpus object.

The `show`-method will show basic information on the corpus object.

Applying the `$`-method on a corpus will return the values for the s-attribute stated with argument `name`.

Use `get_info` to get the the content of the info file for the corpus (usually in the data directory of the corpus) and return it as a character vector. Returns NULL if there is not info file.

The `show_info`-method will get the content of the info file for a corpus, turn it into an html document, and show the result in the viewer pane of RStudio. If the filename of the info file ends on "md", the document is rendered as markdown.

Examples

```r
# get/show information on corpora
corpus("REUTERS") %>% get_info()
corpus("REUTERS") %>% show_info()
corpus("GERMAPARLMINI") %>% get_info()
corpus("GERMAPARLMINI") %>% show_info()

# show-method
if (interactive()) corpus("REUTERS") %>% show()
if (interactive()) corpus("REUTERS") # show is called implicitly

# get corpus ID
corpus("REUTERS") %>% get_corpus()

# use $ to access s_attributes quickly
use("polmineR")
g <- corpus("GERMAPARLMINI")
g$date
corpus("GERMAPARLMINI")$date #
corpus("GERMAPARLMINI") %>% s_attributes(s_attribute = "date") # equivalent

use("polmineR")
sc <- subset("GERMAPARLMINI", date == "2009-10-27")
sc$date
```
Description

Count all tokens, or number of occurrences of a query (CQP syntax may be used), or matches for
the query.

Usage

count(.Object, ...)

## S4 method for signature 'partition'
count(
  .Object,
  query = NULL,
  cqp = is.cqp,
  check = TRUE,
  breakdown = FALSE,
  decode = TRUE,
  p_attribute =getOption("polmineR.p_attribute"),
  mc =getOption("polmineR.cores"),
  verbose = TRUE,
  progress = FALSE,
  phrases = NULL,
  ...
)

## S4 method for signature 'subcorpus'
count(
  .Object,
  query = NULL,
  cqp = is.cqp,
  check = TRUE,
  breakdown = FALSE,
  decode = TRUE,
  p_attribute =getOption("polmineR.p_attribute"),
  mc =getOption("polmineR.cores"),
  verbose = TRUE,
  progress = FALSE,
  phrases = NULL,
  ...
)

## S4 method for signature 'partition_bundle'
count(
  .Object,
query = NULL,
cqp = FALSE,
p_attribute = NULL,
phrases = NULL,
freq = FALSE,
total = TRUE,
mc = FALSE,
progress = FALSE,
verbose = FALSE,
... 
)

## S4 method for signature 'subcorpus_bundle'
count(
  .Object,
  query = NULL,
cqp = FALSE,
p_attribute = NULL,
phrases = NULL,
freq = FALSE,
total = TRUE,
mc = FALSE,
progress = TRUE,
verbose = FALSE,
... 
)

## S4 method for signature 'corpus'
count(
  .Object,
  query = NULL,
cqp = is.cqp,
check = TRUE,
p_attribute = getOption("polmineR.p_attribute"),
breakdown = FALSE,
sort = FALSE,
decode = TRUE,
verbose = TRUE,
... 
)

## S4 method for signature 'character'
count(
  .Object,
  query = NULL,
cqp = is.cqp,
check = TRUE,
p_attribute = getOption("polmineR.p_attribute"),
count

breakdown = FALSE,
sort = FALSE,
decode = TRUE,
verbose = TRUE,
...
)

## S4 method for signature 'vector'
count(.Object, corpus, p_attribute, ...)

## S4 method for signature 'remote_corpus'
count(.Object, ...)

## S4 method for signature 'remote_subcorpus'
count(.Object, ...)

Arguments

LObject A partition or partition_bundle, or a length-one character vector providing the name of a corpus.
...
Further arguments. If .Object is a remote_corpus object, the three dots (...) are used to pass arguments. Hence, it is necessary to state the names of all arguments to be passed explicitly.

query A character vector (one or multiple terms), CQP syntax can be used.
cqp Either logical (TRUE if query is a CQP query), or a function to check whether query is a CQP query or not (defaults to is.query auxiliary function).
check A logical value, whether to check validity of CQP query using check_cqp_query.
breakdown Logical, whether to report number of occurrences for different matches for a query.
decode Logical, whether to turn token ids into decoded strings (only if query is NULL).
p_attribute The p-attribute(s) to use.
mc Logical, whether to use multicore (defaults to FALSE).
verbose Logical, whether to be verbose.
progress Logical, whether to show progress bar.
phrases A phrases object. If provided, the denoted regions will be concatenated as phrases.

freq Logical, if FALSE, counts will be reported, if TRUE, (relative) frequencies are added to table.
total Defaults to FALSE, if TRUE, the total value of counts (column named 'TOTAL') will be amended to the data table that is returned.
sort Logical, whether to sort table with counts (in stat slot).
corpus The name of a CWB corpus.
Details

If .Object is a partition_bundle, the data.table returned will have the queries in the columns, and as many rows as there are in the partition_bundle.

If .Object is a length-one character vector and query is NULL, the count is performed for the whole partition.

If breakdown is TRUE and one query is supplied, the function returns a frequency breakdown of the results of the query. If several queries are supplied, frequencies for the individual queries are retrieved.

Multiple queries can be used for argument query. Some care may be necessary when summing up the counts for the individual queries. When the CQP syntax is used, different queries may yield the same match result, so that the sum of all individual query matches may overestimate the true number of unique matches. In the case of overlapping matches, a warning message is issued. Collapsing multiple CQP queries into a single query (separating the individual queries by "|

Value

A data.table if argument query is used, a count-object, if query is NULL and .Object is a character vector (referring to a corpus) or a partition, a count_bundle-object, if .Object is a partition_bundle.

References

See Also

For a metadata-based breakdown of counts (i.e. tabulation by s-attributes), see dispersion. The hits is the worker behind the dispersion method and offers a similar, yet more low-level functionality as compared to the count method. Using the hits method may be useful to obtain the data required for flexible cross-tabulations.

Examples

use("polmineR")

debates <- partition("GERMAPARLMINI", date = ".*", regex=TRUE)
count(debates, query = "Arbeit") # get frequencies for one token
count(debates, c("Arbeit", "Freizeit", "Zukunft")) # get frequencies for multiple tokens

count("GERMAPARLMINI", query = c("Migration", "Integration"), p_attribute = "word")

derbates <- partition_bundle(
    "GERMAPARLMINI", s_attribute = "date", values = NULL,
    mc = FALSE, verbose = FALSE
)
y <- count(debates, query = "Arbeit", p_attribute = "word")
y <- count(debates, query = c("Arbeit", "Migration", "Zukunft"), p_attribute = "word")

count("GERMAPARLMINI", "Integration.*", breakdown = TRUE)
P <- partition("GERMAPARLMINI", date = "2009-11-11")
count(P, "Integration.*", breakdown = TRUE)

sc <- corpus("GERMAPARLMINI") %>% subset(party == "SPD")
phr <- cpos(sc, query = "Deutsche.*" "Bundestag.*", cqp = TRUE) %>
  as.phrases(corpus = "GERMAPARLMINI", enc = "latin1")
cnt <- count(sc, phrases = phr, p_attribute = "word")

# Multiple queries and overlapping query matches. The first count
# operation will issue a warning that matches overlap, see the second
# example for a solution.
corpus("REUTERS") %>%
  count(query = c(".*oil", "turmoil"), cqp = TRUE)
corpus("REUTERS") %>%
  count(query = "(.*oil|turmoil)"", cqp =TRUE)

count_class

**Count class.**

**Description**

S4 class to organize counts. The classes polmineR and ngrams inherit from the class.

**Usage**

```r
## S4 method for signature 'count'
summary(object)

## S4 method for signature 'count'
length(x)

## S4 method for signature 'count'
hist(x, ...)
```

**Arguments**

- `object` A count object.
- `x` A count object, or a class inheriting from count.
- `...` Further parameters.

**Details**

The `summary-method` in combination with a weighed count-object can be used to perform a dictionary-based sentiment analysis (see examples).

The `length-method` is synonymous with the `size-method` and will return the size of the corpus or partition a count has been derived from.
Slots

- **stat**: Object of class `data.table`.
- **corpus**: Object of class `character`, the CWB corpus the partition is based on.
- **encoding**: Object of class `character`, the encoding of the corpus.
- **name**: Object of class `character`, a name for the object.
- **size**: Object of class `integer`, the size of the partition or corpus the count is based upon.

Author(s)

Andreas Blaette

See Also

The count-class inherits from the `textstat-class`

Examples

```r
# sample for dictionary-based sentiment analysis
weights <- data.table::data.table(
  word = c("gut", "super", "herrlich", "schlecht", "grob", "mies"),
  weight = c(1,1,1,-1,-1,-1)
)
corp <- corpus("GERMAPARLMINI")
sc <- subset(corp, date == "2009-11-11")
cnt <- count(sc, p_attribute = "word")
cnt <- weigh(cnt, with = weights)
y <- summary(cnt)

# old, partition-based workflow
p <- partition("GERMAPARLMINI", date = "2009-11-11")
p <- enrich(p, p_attribute = "word")
weights <- data.table::data.table(
  word = c("gut", "super", "herrlich", "schlecht", "grob", "mies"),
  weight = c(1,1,1,-1,-1,-1)
)
p <- weigh(p, with = weights)
summary(p)
```

cpos

*Get corpus positions for a query or queries.*

Description

Get matches for a query in a CQP corpus (subcorpus, partition etc.), optionally using the CQP syntax of the Corpus Workbench (CWB).
Usage

cpos(.Object, ...)

## S4 method for signature 'corpus'
cpos(
  .Object,
  query,
  p_attribute = getOption("polmineR.p_attribute"),
  cqp = is.cqp,
  regex = FALSE,
  check = TRUE,
  verbose = TRUE,
  ...
)

## S4 method for signature 'character'
cpos(
  .Object,
  query,
  p_attribute = getOption("polmineR.p_attribute"),
  cqp = is.cqp,
  check = TRUE,
  verbose = TRUE,
  ...
)

## S4 method for signature 'slice'
cpos(
  .Object,
  query,
  cqp = is.cqp,
  check = TRUE,
  p_attribute = getOption("polmineR.p_attribute"),
  verbose = TRUE,
  ...
)

## S4 method for signature 'partition'
cpos(
  .Object,
  query,
  cqp = is.cqp,
  check = TRUE,
  p_attribute = getOption("polmineR.p_attribute"),
  verbose = TRUE,
  ...
)
## S4 method for signature 'subcorpus'
cpos(
  .Object,
  query,
  cqp = is.cqp,
  check = TRUE,
  p_attribute = getOption("polmineR.p_attribute"),
  verbose = TRUE,
  ...
)

## S4 method for signature 'matrix'
cpos(.Object)

## S4 method for signature 'hits'
cpos(.Object)

## S4 method for signature `\`NULL`'
cpos(.Object)

### Arguments

- **.Object**: A length-one character vector indicating a CWB corpus, a partition object, or a matrix with corpus positions.
- **...**: Used for reasons of backwards compatibility to process arguments that have been renamed (e.g. `pAttribute`).
- **query**: A character vector providing one or multiple queries (token or CQP query). Token ids (i.e. integer values) are also accepted.
- **p_attribute**: The p-attribute to search. Needs to be stated only if query is not a CQP query. Defaults to NULL.
- **cqp**: Either logical (TRUE if query is a CQP query), or a function to check whether query is a CQP query or not (defaults to `is.cqp` auxiliary function).
- **regex**: Interpret query as a regular expression.
- **check**: A logical value, whether to check validity of CQP query using `check_cqp_query`.
- **verbose**: A logical value, whether to show messages.

### Details

If the `cpos()`-method is applied on a character or partition object, the result is a two-column matrix with the regions (start end end corpus positions of the matches) for a query. CQP syntax can be used. The encoding of the query is adjusted to conform to the encoding of the CWB corpus. If there are not matches, NULL is returned.

If the `cpos()`-method is called on a matrix object, the `cpos` matrix is unfolded, the return value is an integer vector with the individual corpus positions.

If `.Object` is a `hits` object, an integer vector is returned with the individual corpus positions.
. If .Object is a matrix, it is assumed to be a region matrix, i.e. a two-column matrix with left and right corpus positions in the first and second row, respectively. For many operations, such as decoding the token stream, it is necessary to inflate the denoted regions into a vector of all corpus positions referred to by the regions defined in the matrix. The cpos-method for matrix objects will perform this task robustly.

If .Object is NULL, the method will return an empty integer vector. Used internally to handle NULL objects that may be returned from the cpos-method if no matches are obtained for a query.

Value

Unless .Object is a matrix, the return value is a matrix with two columns. The first column reports the left/starting corpus positions (cpos) of the hits obtained. The second column reports the right/ending corpus positions of the respective hit. The number of rows is the number of hits. If there are no hits, a NULL object is returned.

Examples

use("polmineR")

# looking up single tokens
cpos("REUTERS", query = "oil")
corpus("REUTERS") %>% cpos(query = "oil")
corpus("REUTERS") %>% subset(grepl("saudi-arabia", places)) %>% cpos(query = "oil")
partition("REUTERS", places = "saudi-arabia", regex = TRUE) %>% cpos(query = "oil")

# using CQP query syntax
cpos("REUTERS", query = "'Saudi" "Arabia'")
corpus("REUTERS") %>% cpos(query = "'Saudi" "Arabia'")
corpus("REUTERS") %>%
  subset(grepl("saudi-arabia", places)) %>%
  cpos(query = "'Saudi" "Arabia'", cqp = TRUE)
partition("REUTERS", places = "saudi-arabia", regex = TRUE) %>%
  cpos(query = "'Saudi" "Arabia'", cqp = TRUE)

Tools for CQP queries.

Description

Test whether a character string is a CQP query, or turn a character vector into CQP queries.

Usage

is.cqp(query)

check_cqp_query(query, warn = TRUE)

as.cqp(query, normalise.case = FALSE, collapse = FALSE)
Arguments

query A character vector with at least one CQP query.
warn A (length-one) logical value, whether to issue a warning if a query may be buggy.
normalise.case A logical value, if TRUE, a flag will be added to the query/queries to omit matching case.
collapse A logical value, whether to collapse the queries into one.

Details

The is.cqp function guesses whether query is a CQP query and returns the respective logical value (TRUE/FALSE).
The as.cqp function takes a character vector as input and converts it to a CQP query by putting the individual strings in quotation marks.
The check_cqp_query-function will check that opening quotation marks are matched by closing quotation marks, to prevent crashes of CQP and the R session.

Value

is.cqp returns a logical value, as.cqp a character vector, check_cqp_query a logical value that is TRUE if all queries are valid, or FALSE if not.

References

CQP Query Language Tutorial (http://cwb.sourceforge.net/files/CQP_Tutorial.pdf)

Examples

is.cqp("migration") # will return FALSE
is.cqp("migration") # will return TRUE
is.cqp('[pos = "ADJA"] "migration") # will return TRUE

as.cqp("migration")
as.cqp(c("migration", "diversity"))
as.cqp(c("migration", "diversity"), collapse = TRUE)
as.cqp("migration", normalise.case = TRUE)

check_cqp_query("Integration.*") # TRUE, the query is ok
check_cqp_query("Integration.*") # FALSE, closing quotation mark is missing
check_cqp_query("Integration.*") # FALSE, closing quotation mark is missing
check_cqp_query(c("Integration.*", "Integration.*")) # FALSE too
**decode**

*Decode corpus or subcorpus.*

**Description**

Decode corpus or subcorpus and return class specified by argument to.

**Usage**

```
decode(.Object, ...) 
```

### S4 method for signature 'corpus'

```
decode(
  .Object,
  to = c("data.table", "Annotation"),
  p_attributes = NULL,
  s_attributes = NULL,
  decode = TRUE,
  verbose = TRUE
)
```

### S4 method for signature 'character'

```
decode(
  .Object,
  to = c("data.table", "Annotation"),
  s_attributes = NULL,
  p_attributes = NULL,
  decode = TRUE,
  verbose = TRUE,
  ...
)
```

### S4 method for signature 'slice'

```
decode(
  .Object,
  to = "data.table",
  s_attributes = NULL,
  p_attributes = NULL,
  decode = TRUE,
  verbose = TRUE
)
```

### S4 method for signature 'partition'

```
decode(
  .Object,
  to = "data.table",
  s_attributes = NULL,
  ...
)
```
### Arguments

- **.Object** The corpus or subcorpus to decode.
- **...** Further arguments.
- **to** The class of the returned object, stated as a length-one character vector.
- **p_attributes** The positional attributes to decode. If NULL (default), all positional attributes will be decoded.
- **s_attributes** The structural attributes to decode. If NULL (default), all structural attributes will be decoded.
- **decode** A logical value, whether to decode token ids and struc ids to character strings. If FALSE, the values of columns for p- and s-attributes will be integer vectors. If TRUE (default), the respective columns are character vectors.
- **verbose** A logical value, whether to output progress messages.
- **corpus** A CWB indexed corpus, either a length-one character vector, or a corpus object.
- **boost** A length-one logical value, whether to speed up decoding a long vector of token ids by directly reading in the lexion file from the data directory of a corpus. If NULL (default), the internal decision rule is that boost will be TRUE if the corpus is larger than 10 000 000 million tokens and more than 5 percent of the corpus are to be decoded.

### Details

The primary purpose of the method is type conversion. By obtaining the corpus or subcorpus in the format specified by the argument to, the data can be processed with tools that do not rely on the
Corpus Workbench (CWB). Supported output formats are data.table (which can be converted to a data.frame or tibble easily) or an Annotation object as defined in the package NLP. Another purpose of decoding the corpus can be to rework it, and to re-import it into the CWB (e.g. using the cwbtools-package).

An earlier version of the method included an option to decode a single s-attribute, which is not supported any more. See the s_attribute_decode function of the package RcppCWB.

If .Object is an integer vector, it is assumed to be a vector of integer ids of p-attributes. The decode-method will translate token ids to string values as efficiently as possible. The approach taken will depend on the corpus size and the share of the corpus that is to be decoded. To decode a large number of integer ids, it is more efficient to read the lexicon file from the data directory directly and to index the lexicon with the ids rather than relying on RcppCWB::cl_id2str. The internal decision rule is to use the lexicon file when the corpus is larger than 10 000 000 million tokens and more than 5 percent of the corpus are to be decoded. The encoding of the character vector that is returned will be the coding of the locale (usually ISO-8859-1 on Windows, and UTF-8 on macOS and Linux machines).

The decode-method for data.table objects will decode token ids (column '[p-attribute]_id'), adding the corresponding string as a new column. If a column "cpos" with corpus positions is present, ids are derived for the corpus positions given first. If the data.table neither has a column "cpos" nor columns with token ids (i.e. columnn name ending with "_id"), the input data.table is returned unchanged. Note that columns are added to the data.table in an in-place operation to handle memory parsimoniously.

Value

The return value will correspond to the class specified by argument to.

See Also

To decode a structural attribute, you can use the s_attributes-method, setting argument unique as FALSE and s_attribute_decode. See as.VCorpus to decode a partition_bundle object, returning a VCorpus object.

Examples

use("polmineR")

# Decode corpus as data.table
dt <- decode("GERMAPARLMINI", to = "data.table")

# Decode corpus selectively
dt <- decode("GERMAPARLMINI", to = "data.table", p_attributes = "word", s_attributes = "party")

# Decode a subcorpus
sc <- subset(corpus("GERMAPARLMINI"), speaker == "Angela Dorothea Merkel")
dt <- decode(sc, to = "data.table")

# Decode subcorpus selectively
dt <- decode(sc, to = "data.table", p_attributes = "word", s_attributes = "party")
dispersion

Dispersion of a query or multiple queries.

Description

The method returns counts (optionally frequencies) of a query or a multiple queries in subcorpora defined by one or two s-attributes.

Usage

dispersion(.Object, ...)

## S4 method for signature 'slice'
dispersion(...)

## S4 method for signature 'partition'

dispersion(
  .Object,
  query,
  s_attribute,
  cqp = FALSE,
  p_attribute = getOption("polmineR.p_attribute"),
  freq = FALSE,
  mc = FALSE,
  progress = FALSE,
  verbose = FALSE,
  ...
)

## S4 method for signature 'subcorpus'

dispersion(
  .Object,
  query,
  s_attribute,
  cqp = FALSE,
  p_attribute = getOption("polmineR.p_attribute"),
  freq = FALSE,
  mc = FALSE,
  progress = TRUE,
  verbose = FALSE,
  ...
)

## S4 method for signature 'corpus'

dispersion(
  .Object,
  query,
  s_attribute,
  cqp = is.cqp,
  p_attribute = getOption("polmineR.p_attribute"),
  freq = FALSE,
mc = FALSE,
progress = FALSE,
verbose = FALSE,
...)

## S4 method for signature 'character'
dispersion(
  .Object,
  query,
  s_attribute,
  cqp = is.cqp,
  p_attribute = getOption("polmineR.p_attribute"),
  freq = FALSE,
  mc = FALSE,
  progress = TRUE,
  verbose = TRUE,
  ...
)

## S4 method for signature 'hits'
dispersion(.Object, source, s_attribute, freq = FALSE, verbose = TRUE, ...)

## S4 method for signature 'remote_corpus'
dispersion(.Object, ...)

## S4 method for signature 'remote_subcorpus'
dispersion(.Object, ...)

Arguments

.Object A partition object or a corpus provided by a character string.

... Further parameters.

query A character vector stating one or multiple queries.

s_attribute A character vector (length 1 or 2) providing s-attributes.

cqp If logical, whether the query is a CQP query, if it is a function that is passed in, the function will be applied to the query to guess whether query is a CQP query

p_attribute Length one character vector, the p-attribute that will be looked up (typically 'word' or 'lemma').

freq A logical value, whether to calculate normalized frequencies.

mc A logical value, whether to use multicore.

progress A logical value, whether to show progress.

verbose A logical value, whether to be verbose.

source The source of the evaluation the hits reported in .Object are based on, a corpus, subcorpus or partition object.
Value
depends on the input, as this is a wrapper function
A data.table.

Author(s)
Andreas Blaette

See Also
The worker behind the dispersion-method is the hits-method.

count

Examples
use("polmineR")
dispersion("GERMAPARLMINI", query = "Integration", s_attribute = "date")

test <- partition("GERMAPARLMINI", date = ".\*", p_attribute = NULL, regex = TRUE)
integration <- dispersion(
  test, query = "Integration",
  p_attribute = "word", s_attribute = "date"
)
integration <- dispersion(test, "Integration", s_attribute = c("date", "party"))
integration <- dispersion(test, "Integration.\*", s_attribute = "date", cqp = TRUE)

dotplot

Description
dotplot

Usage
dotplot(.Object, ...)

## S4 method for signature 'textstat'
dotplot(.Object, col, n = 20L, ...)

## S4 method for signature 'features'
dotplot(.Object, col = NULL, n = 20L, ...)

## S4 method for signature 'features_ngrams'
dotplot(.Object, col = NULL, n = 20L, ...)

## S4 method for signature 'partition'
dotplot(.Object, col = "count", n = 20L, ...)
Arguments

.object object
... further arguments that will be passed into the dotchart function
.col column
.n number

encoding Get and set encoding.

Description

Method for textstat objects and classes inheriting from textstat; if object is a character vector, the encoding of the corpus is returned.

Usage

encoding(object)

encoding(object) <- value

## S4 method for signature 'textstat'
encoding(object)

## S4 method for signature 'bundle'
encoding(object)

## S4 method for signature 'character'
encoding(object)

## S4 method for signature 'corpus'
encoding(object)

## S4 method for signature 'subcorpus'
encoding(object)

Arguments

.object A textstat or bundle object, or a length-one character vector specifying a corpus.
.value Value to be assigned.
Examples

```r
# Get encoding of a corpus.
encoding("REUTERS")

# Get encoding of a partition.
r <- partition("REUTERS", places = "kuwait", regex = TRUE)
encoding(r)

# Get encoding of another class inheriting from textstat (count).
cnt <- count("REUTERS", p_attribute = "word")
encoding(cnt)

# Get encoding of objects in a bundle.
pb <- partition_bundle("REUTERS", s_attribute = "id")
encoding(pb)
```

encodings

Conversion between corpus and native encoding.

Description

Utility functions to convert encoding between the native encoding and the encoding of the corpus.

Usage

```r
as.utf8(x, from)

as.nativeEnc(x, from)

as.corpusEnc(x, from = localeToCharset()[1], corpusEnc)
```

Arguments

- `x` the object (a character vector)
- `from` encoding of the input character vector
- `corpusEnc` encoding of the corpus (e.g. "latin1", "UTF-8")

Details

The encoding of a corpus and the encoding of the terminal (the native encoding) may differ and evoke strange output, or wrong results if no conversion is carried out between the potentially differing encodings. The functions `as.nativeEnc` and `as.corpusEnc` are auxiliary functions to assist this. The functions `as.nativeEnc` and `as.utf8` deliberately remove the explicit statement of the encoding, to avoid warnings that may occur with character vector columns in a `data.table` object.
enrich

**Enrich an object.**

**Description**
Methods to enrich objects with additional (statistical) information. The methods are documented with the classes to which they adhere. See the references in the `seealso`-section.

**Usage**
enrich(.Object, ...)

**Arguments**

- `.Object` a partition, partition_bundle or comp object
- `...` further parameters

**See Also**
The enrich method is defined for the following classes: "partition", (see `partition_class`), "partition_bundle" (see `partition_bundle-class`), "kwic" (see `kwic-class`), and "context" (see `context-class`). See the linked documentation to learn how the enrich method can be applied to respective objects.

features

**Get features by comparison.**

**Description**
The features of two objects, usually a partition defining a corpus of interest (coi), and a partition defining a reference corpus (ref) are compared. The most important purpose is term extraction.

**Usage**
features(x, y, ...)

```r
## S4 method for signature 'partition'
features(x, y, included = FALSE, method = "chisquare", verbose = FALSE)

## S4 method for signature 'count'
features(x, y, by = NULL, included = FALSE, method = "chisquare",
```
features

verbose = TRUE
)

## S4 method for signature 'partition_bundle'
features(
  x,
  y,
  included = FALSE,
  method = "chisquare",
  verbose = TRUE,
  mc = getOption("polmineR.mc"),
  progress = FALSE
)

## S4 method for signature 'count_bundle'
features(
  x,
  y,
  included = FALSE,
  method = "chisquare",
  verbose = !progress,
  mc = getOption("polmineR.mc"),
  progress = FALSE
)

## S4 method for signature 'ngrams'
features(x, y, included = FALSE, method = "chisquare", verbose = TRUE, ...)

## S4 method for signature 'Cooccurrences'
features(x, y, included = FALSE, method = "ll", verbose = TRUE)

Arguments

x A partition or partition_bundle object.
y A partition object, it is assumed that the coi is a subcorpus of ref
... further parameters
included TRUE if coi is part of ref, defaults to FALSE
method the statistical test to apply (chisquare or log likelihood)
verbose A logical value, defaults to TRUE
by the columns used for merging, if NULL (default), the p-attribute of x will be used
mc logical, whether to use multicore
progress logical

Author(s)

Andreas Blaette
References

Examples

```r
use("polmineR")

kaufer <- partition(
  "GERMAPARLMINI",
  speaker = "Volker Kauder", interjection = "speech",
  p_attribute = "word"
)
all <- partition("GERMAPARLMINI", interjection = "speech", p_attribute = "word")
terms_kaufer <- features(x = kaufer, y = all, included = TRUE)
top100 <- subset(terms_kaufer, rank_chisquare <= 100)
head(top100)

# a different way is to compare count objects
kaufer_count <- as(kaufer, "count")
all_count <- as(all, "count")
terms_kaufer <- features(kaufer_count, all_count, included = TRUE)
top100 <- subset(terms_kaufer, rank_chisquare <= 100)
head(top100)

speakers <- partition_bundle("GERMAPARLMINI", s_attribute = "speaker")
speakers <- enrich(speakers, p_attribute = "word")
speaker_terms <- features(speakers[[1:5]], all, included = TRUE, progress = TRUE)
dtm <- as.DocumentTermMatrix(speaker_terms, col = "chisquare")
# Get features of objects in a count_bundle
ref <- corpus("GERMAPARLMINI") %>% count(p_attribute = "word")
cois <- corpus("GERMAPARLMINI") %>%
  subset(speaker %in% c("Angela Dorothea Merkel", "Hubertus Heil")) %>%
  split(s_attribute = "speaker") %>%
  count(p_attribute = "word")
y <- features(cois, ref, included = TRUE, method = "chisquare", progress = TRUE)
```

features-class Feature selection by comparison.

Description

The features-method returns a features-object. Several features-objects can be combined into a features_bundle-object.
Usage

## S4 method for signature 'features'
summary(object)

## S4 method for signature 'features'
show(object)

## S4 method for signature 'features_bundle'
summary(object)

## S4 method for signature 'features'
format(x, digits = 2L)

## S4 method for signature 'features'
view(.Object)

Arguments

object A features or features_bundle object.

x A features object.

digits Integer indicating the number of decimal places (round) or significant digits (signif) to be used.

.Object a features object.

Details

A set of features objects can be combined into a features_bundle. Typically, a features_bundle will result from applying the features-method on a partition_bundle. See the documentation for bundle to learn about the methods for bundle objects that are available for a features_bundle.

Slots

corpus The CWB corpus the features are derived from, a character vector of length 1.
p_attribute Object of class character.
encoding Object of class character.
corpus Object of class character.
stat Object of class data.frame.
size_coi Object of class integer.
size_ref Object of class integer.
included Object of class logical whether corpus of interest is included in reference corpus
method Object of class character statisticalTest used
call Object of class character the call that generated the object

Author(s)

Andreas Blaette
get_template  Get template for reconstructing full text.

Description

Templates are used to format the markdown/html output of partitions.

Usage

get_template(.Object, ...)  

## S4 method for signature 'character'
get_template(.Object, warn = FALSE)

## S4 method for signature 'corpus'
get_template(.Object, warn = FALSE)

## S4 method for signature 'partition'
get_template(.Object, warn = FALSE)

## S4 method for signature 'subcorpus'
get_template(.Object, warn = FALSE)

Arguments

/Object/  A corpus, subcorpus or partition object, or a length-one character vector with a corpus ID.
...      Further arguments to be defined.
warn     A logical value, whether to issue a warning if template is not available. Defaults to FALSE.

get_token_stream  Get Token Stream.

Description

Auxiliary method to get the fulltext of a corpus, subcorpora etc. Can be used to export corpus data to other tools.
get_token_stream

Usage

get_token_stream(.Object, ...)

## S4 method for signature 'numeric'
get_token_stream(
  .Object,
  corpus,
  p_attribute,
  subset = NULL,
  boost = NULL,
  encoding = NULL,
  collapse = NULL,
  beautify = TRUE,
  cpos = FALSE,
  cutoff = NULL,
  decode = TRUE,
  ...
)

## S4 method for signature 'matrix'
get_token_stream(.Object, ...)

## S4 method for signature 'corpus'
get_token_stream(.Object, left = NULL, right = NULL, ...)

## S4 method for signature 'character'
get_token_stream(.Object, left = NULL, right = NULL, ...)

## S4 method for signature 'slice'
get_token_stream(.Object, p_attribute, collapse = NULL, cpos = FALSE, ...)

## S4 method for signature 'partition'
get_token_stream(.Object, p_attribute, collapse = NULL, cpos = FALSE, ...)

## S4 method for signature 'subcorpus'
get_token_stream(.Object, p_attribute, collapse = NULL, cpos = FALSE, ...)

## S4 method for signature 'regions'
get_token_stream(
  .Object,
  p_attribute = "word",
  collapse = NULL,
  cpos = FALSE,
  ...
)

## S4 method for signature 'partition_bundle'
get_token_stream(}
get_token_stream

Arguments

,Object
  p_attribute = "word",
  phrases = NULL,
  subset = NULL,
  collapse = NULL,
  cpos = FALSE,
  decode = TRUE,
  verbose = TRUE,
  progress = FALSE,
  mc = FALSE,
...)

_Arguments

 OBJECT Input object.
...
Arguments that will be be passed into the get_token_stream-method for a numeric vector, the real worker.

 corpus A CWB indexed corpus.

 p_attribute A length-one character vector, the p-attribute to decode.

 subset An expression applied on p-attributes, using non-standard evaluation. Note that symbols used in the expression may not be used internally (e.g. 'stopwords').

 boost A length-one logical value, whether to speed up decoding a long vector of token ids by directly by reading in the lexion file from the data directory of a corpus. If NULL (default), the internal decision rule is that boost will be TRUE if the corpus is larger than 10 000 000 million tokens and more than 5 percent of the corpus are to be decoded.

 encoding If not NULL (default) a length-one character vector stating an encoding that will be assigned to the (decoded) token stream.

 collapse If not NULL (default), a length-one character string passed into paste to collapse character vector into a single string.

 beautify A (length-one) logical value, whether to adjust whitespace before and after interpunctation.

 cpos A logical value, whether to return corpus positions as names of the tokens.

cutoff Maximum number of tokens to be reconstructed.

decode A (length-one) logical value, whether to decode token ids to character strings. Defaults to TRUE, if FALSE, an integer vector with token ids is returned.

 left Left corpus position.

 right Right corpus position.

 phrases A phrases object. Defined phrases will be concatenated.

 verbose A length-one logical value, whether to show messages.

 progress A length-one logical value, whether to show progress bar.

 mc Number of cores to use. If FALSE (default), only one thread will be used.
get_token_stream

Details

CWB indexed corpora have a fixed order of tokens which is called the *token stream*. Every token is assigned to a unique *corpus position*. Subsets of the (entire) token stream defined by a left and a right corpus position are called *regions*. The `get_token_stream`-method will extract the tokens (for regions) from a corpus.

The primary usage of this method is to return the token stream of a (sub-)corpus as defined by a corpus, subcorpus or partition object. The methods defined for a numeric vector or a (two-column) matrix defining regions (i.e. left and right corpus positions in the first and second column) are the actual workers for this operation.

The `get_token_stream` has been introduced so serve as a worker by higher level methods such as `read`, `html`, and `as.markdown`. It may however be useful for decoding a corpus so that it can be exported to other tools.

Examples

```r
# Decode first words of GERMAPARLMINI corpus (first sentence)
get_token_stream(0:9, corpus = "GERMAPARLMINI", p_attribute = "word")

# Decode first sentence and collapse tokens into single string
get_token_stream(0:9, corpus = "GERMAPARLMINI", p_attribute = "word", collapse = " ")

# Decode regions defined by two-column matrix
region_matrix <- matrix(c(0,9,10,25), ncol = 2, byrow = TRUE)
get_token_stream(region_matrix, corpus = "GERMAPARLMINI", p_attribute = "word", encoding = "latin1")

# Use argument 'beautify' to remove surplus whitespace
get_token_stream(
  region_matrix,
  corpus = "GERMAPARLMINI",
  p_attribute = "word",
  encoding = "latin1",
  collapse = " ", beautify = TRUE
)

# Decode entire corpus (corpus object / specified by corpus ID)
fulltext <- get_token_stream("GERMAPARLMINI", p_attribute = "word")
corpus("GERMAPARLMINI") %>%
  get_token_stream(p_attribute = "word") %>%
  head()

# Decode subcorpus
corpus("REUTERS") %>%
  subset(id == "127") %>%
  get_token_stream(p_attribute = "word") %>%
  head()

# Decode partition_bundle
pb_tokstr <- corpus("REUTERS") %>%
  split(s_attribute = "id") %>%
  get_token_stream(p_attribute = "word")
```
# Get token stream for partition_bundle

pb <- partition_bundle("REUTERS", s_attribute = "id")

## Workflow to filter decoded subcorpus_bundle
## Not run:  

sp <- corpus("GERMAPARLMINI") %>% as.speeches(s_attribute_name = "speaker", progress = FALSE)

queries <- c("freiheitliche" "Grundordnung", "Bundesrepublik" "Deutschland")

phr <- corpus("GERMAPARLMINI") %>% cpos(query = queries) %>% as.phrases(corpus = "GERMAPARLMINI")

kill <- tm::stopwords("de")

## End(Not run)

gt <- get_token_stream(
    sp,
    p_attribute = c("word", "pos"),
    subset = {!word %in% kill & !grepl("(\$.|$ART)", pos)},
    phrases = phr,
    progress = FALSE,
    verbose = FALSE
)

## End(Not run)

---

### get_type

**Get corpus/partition type.**

**Description**

To generate fulltext output, different templates can be used with a behavior that depends on the type of a corpus. `get_type` will return the type of corpus if it is a specialized one, or NULL.

**Usage**

```r
get_type(.Object)
```

## S4 method for signature 'corpus'

```r
get_type(.Object)
```

## S4 method for signature 'character'

```r
get_type(.Object)
```

## S4 method for signature 'partition'

```r
get_type(.Object)
```

## S4 method for signature 'subcorpus'

```r
get_type(.Object)
```

## S4 method for signature 'partition_bundle'

```r
get_type(.Object)
```
## S4 method for signature 'subcorpus_bundle'
get_type(.Object)

**Arguments**

/Object/ A partition, partition_bundle, Corpus object, or a length-one character vector indicating a CWB corpus.

**Details**

When generating a partition, the corpus type will be prefixed to the class that is generated (separated by underscore). If the corpus type is not NULL, a class inheriting from the partition-class is instantiated. Note that at this time, only plpr_partition and press_partition is implemented.

**Examples**

```r
use("polmineR")
get_type("GERMAPARLMINI")
p <- partition("GERMAPARLMINI", date = "2009-10-28")
get_type(p)
is(p)

pb <- partition_bundle("GERMAPARLMINI", s_attribute = "date")
get_type(pb)

get_type("REUTERS") # returns NULL - no specialized corpus
```

---

**highlight**

*Highlight tokens in text output.*

**Description**

Highlight tokens in fulltext based on exact match, a regular expression or corpus position in kwic output or html document.

**Usage**

highlight(.Object, ...)

```r
## S4 method for signature 'character'
highlight(.Object, highlight = list(), regex = FALSE, perl = FALSE, ...)

## S4 method for signature 'html'
highlight(.Object, highlight = list(), regex = FALSE, perl = FALSE, ...)

## S4 method for signature 'kwic'
```
highlight(
    .Object,
    highlight = list(),
    regex = FALSE,
    perl = TRUE,
    verbose = TRUE,
    ...
)

Arguments

.Object A html, character, a kwic object.

highlight A character vector, or a list of character or integer vectors.

regex Logical, whether character vectors are interpreted as regular expressions.

perl Logical, whether to use perl-style regular expressions for highlighting when regex is TRUE.

verbose Logical, whether to output messages.

Details

If highlight is a character vector, the names of the vector are interpreted as colors. If highlight is a list, the names of the list are considered as colors. Values can be character values or integer values with token ids. Colors are inserted into the output html and need to be digestable for the browser used.

Examples

demo("polmineR")
P <- partition("REUTERS", places = "argentina")
H <- html(P)
Y <- highlight(H, list(lightgreen = "higher"))
if (interactive()) htmltools::html_print(Y)

# highlight matches for a CQP query
H2 <- highlight(
    H,
    highlight = list(yellow = cpos(hits(P, query = "'prod.*'", cqp = TRUE)))
)

# the method can be used in pipe
P %>% html() %>% highlight(list(lightgreen = "1986")) -> H
P %>% html() %>% highlight(list(lightgreen = c("1986", "higher"))) -> H
P %>% html() %>% highlight(list(lightgreen = 4020:4023)) -> H

# use highlight for kwic output
K <- kwic("REUTERS", query = "barrel")
K2 <- highlight(K, highlight = list(yellow = c("oil", "price")))
# use character vector for output, not list
K2 <- highlight(
  K,
  highlight = c(
    green = "pric.",
    red = "reduction",
    red = "decrease",
    orange = "dropped"
  ),
  regex = TRUE
)

## S4 method for signature 'corpus'
hits(.Object, ...)

## S4 method for signature 'character'
hits(.Object, ...

### Description
Get hits for queries, optionally with s-attribute values.

### Usage
hits(.Object, ...)
size = FALSE,
freq = FALSE,
mc = FALSE,
verbose = TRUE,
progress = TRUE,
...
)

## S4 method for signature 'slice'
hits(
  .Object,
  query,
  cqp = FALSE,
  s_attribute = NULL,
  p_attribute = "word",
  size = FALSE,
  freq = FALSE,
  mc = FALSE,
  progress = FALSE,
  verbose = TRUE,
  ...
)

## S4 method for signature 'subcorpus'
hits(
  .Object,
  query,
  cqp = FALSE,
  s_attribute = NULL,
  p_attribute = "word",
  size = FALSE,
  freq = FALSE,
  mc = FALSE,
  progress = FALSE,
  verbose = TRUE,
  ...
)

## S4 method for signature 'partition'
hits(
  .Object,
  query,
  cqp = FALSE,
  s_attribute = NULL,
  p_attribute = "word",
  size = FALSE,
  freq = FALSE,
  mc = FALSE,
## S4 method for signature 'partition_bundle'

```r
hits(
  .Object,
  query,
  cqp = FALSE,
  check = TRUE,
  p_attribute = getOption("polmineR.p_attribute"),
  s_attribute = NULL,
  size = TRUE,
  freq = FALSE,
  mc = getOption("polmineR.mc"),
  progress = FALSE,
  verbose = TRUE,
  ...
)
```

## S4 method for signature 'context'

```r
hits(.Object, s_attribute = NULL, verbose = TRUE, ...)
```

### Arguments

- `.Object` A length-one character vector with a corpus ID, a partition or partition_bundle object
- `...` Further arguments (used for backwards compatibility).
- `query` A character vector (optionally named, see details) with one or more queries.
- `cqp` Either a logical value (TRUE if query is a CQP query), or a function to check whether query is a CQP query or not.
- `check` A logical value, whether to check validity of CQP query using `check_cqp_query`.
- `s_attribute` A character vector of s-attributes that will be reported as metadata.
- `p_attribute` A character vector stating a p-attribute.
- `size` A logical value, whether to report the size of subcorpus.
- `freq` A logical value, whether to report relative frequencies.
- `mc` A logical value, whether to use multicore.
- `verbose` A logical value, whether to output messages.
- `progress` A logical value, whether to show progress bar.

### Details

If the character vector provided by `query` is named, these names will be reported in the data.table that is returned rather than the queries.

If `freq` is TRUE, the data.table returned in the DT-slot will deliberately include the subsets of the partition/corpus with no hits (query is NA, count is 0).
Examples

```r
use("polmineR")

# get hits for corpus object
y <- corpus("REUTERS") %>% hits(query = "oil")
y <- corpus("REUTERS") %>% hits(query = c("oil", "barrel"))
y <- corpus("REUTERS") %>% hits(query = "oil", s_attribute = "places", freq = TRUE)

# specify corpus by corpus ID
y <- hits("REUTERS", query = "oil")
y <- hits("REUTERS", query = "oil", s_attribute = "places", freq = TRUE)

# get hits for partition
p <- partition("REUTERS", places = "saudi-arabia", regex = TRUE)
y <- hits(p, query = "oil")
y <- hits(p, query = "oil", s_attribute = "id")

# get hits for subcorpus
y <- corpus("REUTERS") %>%
  subset(grep("saudi-arabia", places)) %>%
  hits(query = "oil")
```

---

**hits_class**

*Hits class.*

---

**Description**

Hits class.

**Usage**

```r
## S4 method for signature 'hits'
sample(x, size)
```

**Arguments**

- `x` A hits object.
- `size` A non-negative integer giving the number of items to choose.

**Slots**

- `stat` A "data.table"
- `corpus` A "character" vector
- `query` Object of class "character"
- `p_attribute` p-attribute that has been queried
- `encoding` encoding of the corpus
- `name` name of the object
**html**

Generate html from object.

**Description**

Prepare html document to see full text.

**Usage**

```r
html(object, ...)  
## S4 method for signature 'character'
html(object, corpus, height = NULL)
## S4 method for signature 'partition'
html(
  object,
  meta = NULL,
  cpos = TRUE,
  verbose = FALSE,
  cutoff = NULL,
  charoffset = FALSE,
  beautify = TRUE,
  height = NULL,
  ...  
)
## S4 method for signature 'subcorpus'
html(
  object,
  meta = NULL,
  cpos = TRUE,
  verbose = FALSE,
  cutoff = NULL,
  charoffset = FALSE,
  beautify = FALSE,
  height = NULL,
  ...  
)
## S4 method for signature 'partition_bundle'
html(
  object,
  charoffset = FALSE,
  beautify = TRUE,
  height = NULL,
  progress = TRUE,
)```
## S4 method for signature 'kwic'

```r
textobject, i, s_attribute = NULL, type = NULL, verbose = FALSE, ...)
```

### Arguments

- **object**
  - The object the fulltext output will be based on.
- **...**
  - Further parameters that are passed into `as.markdown`.
- **corpus**
  - The ID of the corpus, a length-one character vector.
- **height**
  - A character vector that will be inserted into the html as an optional height of a scroll box.
- **meta**
  - Metadata to include in output, if NULL (default), the s-attributes defining a partition will be used.
- **cpos**
  - Length-one logical value, if TRUE (default), all tokens will be wrapped by elements with id attribute indicating corpus positions.
- **verbose**
  - Length-one logical value, whether to output progress messages.
- **cutoff**
  - An integer value, maximum number of tokens to decode from token stream, passed into `as.markdown`.
- **charoffset**
  - Length-one logical value, if TRUE, character offset positions are added to elements embracing tokens.
- **beautify**
  - Length-one logical value, if TRUE, whitespace before interpunctuation will be removed.
- **progress**
  - Length-one logical value, whether to output progress# bar.
- **i**
  - An integer value: If object is a kwic-object, the index of the concordance for which the fulltext is to be generated.
- **s_attribute**
  - Structural attributes that will be used to define the partition where the match occurred.
- **type**
  - The partition type.

### Details

If param charoffset is TRUE, character offset positions will be added to tags that embrace tokens. This may be useful, if exported html document is annotated with a tool that stores annotations with character offset positions.

### Value

Returns an object of class `html` as used in the `htmltools` package. Methods such as `htmltools::html_print` will be available. The encoding of the html document will be UTF-8 on all systems (including Windows).
Examples

use("polmineR")
P <- partition("REUTERS", places = "argentina")
H <- html(P)
if (interactive()) H # show full text in viewer pane

# html-method can be used in a pipe
H <- partition("REUTERS", places = "argentina") %>% html()

# use html-method to get full text where concordance occurs
K <- kwic("REUTERS", query = "barrels")
H <- html(K, i = 1, s_attribute = "id")
H <- html(K, i = 2, s_attribute = "id")
for (i in 1:length(K)) {
  H <- html(K, i = i, s_attribute = "id")
  if (interactive()){
    show(H)
    userinput <- readline("press 'q' to quit or any other key to continue")
    if (userinput == "q") break
  }
}

kwic

Perform keyword-in-context (KWIC) analysis.

Description

Get concordances for the matches for a query / perform keyword-in-context (kwic) analysis.

Usage

kwic(.Object, ...)

## S4 method for signature 'context'
kwic(
  .Object,
  s_attributes = getOption("polmineR.meta"),
  cpos = TRUE,
  verbose = FALSE,
  ...
)

## S4 method for signature 'slice'
kwic(
  .Object,
  query,
  cqp = is.cqp,
left = getOption("polmineR.left"),
right = getOption("polmineR.right"),
s_attributes = getOption("polmineR.meta"),
p_attribute = "word",
boundary = NULL,
cpos = TRUE,
stoplist = NULL,
positivelist = NULL,
regex = FALSE,
verbose = TRUE,
...)

## S4 method for signature 'partition'
kwic(
  .Object,
  query,
  cqp = is.cqp,
  left = getOption("polmineR.left"),
  right = getOption("polmineR.right"),

## S4 method for signature 'remote_subcorpus'
kwic(.Object, ...)

## S4 method for signature 'partition_bundle'
kwic(.Object, ..., verbose = FALSE)

## S4 method for signature 'subcorpus_bundle'
kwic(.Object, ...)

Arguments

/Object/ A (length-one) character vector with the name of a CWB corpus, a partition or context object.

... Further arguments, used to ensure backwards compatibility. If .Object is a remote_corpus or remote_partition object, the three dots (...) are used to pass arguments. Hence, it is necessary to state the names of all arguments to be passed explicitly.

s_attributes Structural attributes (s-attributes) to include into output table as metainformation.

cpos Logical, if TRUE, a data.table with the corpus positions ("cpos") of the hits and their surrounding context will be assigned to the slot "cpos" of the kwic-object that is returned. Defaults to TRUE, as the availability of the cpos-data.table will often be a prerequisite for further operations on the kwic object. Omitting the table may however be useful to minimize memory consumption.

verbose A logical value, whether to print messages.

query A query, CQP-syntax can be used.

cqp Either a logical value (TRUE if query is a CQP query), or a function to check whether query is a CQP query or not (defaults to auxiliary function is.query).

left Number of tokens to the left of query match.

right Number of tokens to the right of query match.

p_attribute The p-attribute, defaults to 'word'.

boundary If provided, a length-one character vector stating an s-attribute that will be used to check the boundaries of the text.

stoplist Terms or ids to prevent a concordance from occurring in results.

positivelist Terms or ids required for a concordance to occur in results

regex Logical, whether stoplist/positivelist is interpreted as regular expression.

check A logical value, whether to check validity of CQP query using check_cqp_query.

progress A logical value, whether to show progress bar.

Details

The method works with a whole CWB corpus defined by a character vector, and can be applied on a partition- or a context object.

If a positivelist is supplied, only those concordances will be kept that have one of the terms from the positivelist occur in the context of the query match. Use argument regex if the positivelist
should be interpreted as regular expressions. Tokens from the positivelist will be highlighted in the output table.

If a negativelist is supplied, concordances are removed if any of the tokens of the negativelist occurs in the context of the query match.

Applying the kwic-method on a partition_bundle or subcorpus_bundle will return a single kwic object that includes a column 'subcorpus_name' with the name of the subcorpus (or partition) in the input object where the match for a concordance occurs.

Value

If there are no matches, or if all (initial) matches are dropped due to the application of a positivelist, a NULL is returned.

References

See Also

The return value is a kwic-class object; the documentation for the class explains the standard generic methods applicable to kwic-class objects. It is possible to read the whole text where a query match occurs, see the read-method. To highlight terms in the context of a query match, see the highlight-method.

Examples

defuse("polmineR")

# basic usage
K <- kwic("GERMAPARLMINI", "Integration")
if (interactive()) show(K)
oil <- corpus("REUTERS") %>% kwic(query = "oil")
if (interactive()) show(oil)
oil <- corpus("REUTERS") %>%
  kwic(query = "oil") %>%
  highlight(yellow = "crude")
if (interactive()) show(oil)

# increase left and right context and display metadata
K <- kwic("GERMAPARLMINI",
  "Integration", left = 20, right = 20,
  s_attributes = c("date", "speaker", "party")
)
if (interactive()) show(K)

# use CQP syntax for matching
K <- kwic("
"GERMAPARLMINI",
'"Integration" [] "(Menschen|Migrant.*|Personen)"', cqp = TRUE,
left = 20, right = 20,
s_attributes = c("date", "speaker", "party")
)
if (interactive()) show(K)

# check that boundary of region is not transgressed
K <- kwic(
  "GERMAPARLMINI",
  "Sehr" "geehrte"", cqp = TRUE,
  left = 100, right = 100,
  boundary = "date"
)
if (interactive()) show(K)

# use positivelist and highlight matches in context
K <- kwic("GERMAPARLMINI", query = "Integration", positivelist = "[Ee]urop.*", regex = TRUE)
K <- highlight(K, yellow = "[Ee]urop.*", regex = TRUE)

# Apply kwic on partition_bundle/subcorpus_bundle
gparl_2009_11_10_speeches <- corpus("GERMAPARLMINI") %>%
  subset(date == "2009-11-10") %>%
  as.speeches(s_attribute_name = "speaker", progress = FALSE, verbose = FALSE)
k <- kwic(gparl_2009_11_10_speeches, query = "Integration")

## S4 kwic class

**Description**

S4 class for organizing information for kwic/concordance output. A set of standard generics (show, as.character, as.data.frame, length, sample, subset) as well as indexing is implemented to process kwic class objects (see 'Usage'). See section 'Details' for the enrich, view and knit_print methods.

## Usage

### S4 method for signature 'kwic' get_corpus(x)

### S4 method for signature 'kwic' count(.Object, p_attribute = "word")

### S4 method for signature 'kwic' as.DocumentTermMatrix(x, p_attribute, verbose = TRUE, ...)

### S4 method for signature 'kwic' as.TermDocumentMatrix(x, p_attribute, verbose = TRUE, ...)
## S4 method for signature 'kwic'
show(object)

## S4 method for signature 'kwic'
knit_print(x, options = knitr::opts_chunk)

## S4 method for signature 'kwic'
as.character(x, fmt = "<i>%s</i>")

## S4 method for signature 'kwic,ANY,ANY,ANY'
x[i]

## S4 method for signature 'kwic'
subset(x, ...)

## S4 method for signature 'kwic'
as.data.frame(x)

## S4 method for signature 'kwic'
length(x)

## S4 method for signature 'kwic'
sample(x, size)

## S4 method for signature 'kwic_bundle'
merge(x)

## S4 method for signature 'kwic'
enrich(.Object, s_attributes = NULL, extra = NULL, table = FALSE, ...)

## S4 method for signature 'kwic'
format(
x,
  node_color = "blue",
  align = TRUE,
  extra_color = "grey",
  lineview =getOption("polmineR.lineview")
)

## S4 method for signature 'kwic'
view(.Object)

### Arguments

- **x**: A kwic class object.
- **.Object**: A kwic class object.
- **p_attribute**: A length-one character vector supplying a p-attribute.
verbose

A logical value, whether to output debugging messages.

... Used for backwards compatibility.

object

A kwic class object.
	on options

Chunk options.

fmt

A format string passed into sprintf to format the node of a KWIC display.

i

Single integer value, the kwic line for which the fulltext shall be inspected.

size

An integer, subset size for sampling.

s_attributes

Character vector of s-attributes with metainformation.

table

Logical, whether to turn cpos data.table into data.table in slot stat for output.

node_color

If not NULL, the html color of the node. If supplied, the node will be wrapped in respective html tags.

align

A logical value for preparing kwic output. If TRUE, whether the content of the columns 'left', 'node' and 'right' will be wrapped in html div elements that will align the output right, centered and left, respectively.

extra_color

If extra context has been generated using enrich, the html color of the additional output (defaults to 'grey').

lineview

A logical value, whether to concatenate left context, node and right context when preparing kwic output.

Details

Applying the count-method on a kwic object will return a count object with the evaluation of the left and right context of the match.

The knit_print method will be called by knitr to render 'kwic' objects as a DataTable htmlwidget when rendering a R Markdown document as html. It will usually be necessary to explicitly state "render = knit_print" in the chunk options. The option 'polmineR_pagelength' controls the number of lines displayed in the resulting 'htmlwidget'. Note that including htmlwidgets in html documents requires that pandoc is installed. To avoid an error, a formatted data.table is returned by knit_print if pandoc is not available.

The as.character-method will return a list of character vectors, concatenating the columns "left", "node" and "right" of the data.table in the stat-slot of the input kwic-class object. Optionally, the node can be formatted using a format string that is passed into sprintf.

The subset-method will apply subset to the table in the slot stat, e.g. for filtering query results based on metadata (i.e. s-attributes) that need to be present.

The enrich method is used to generate the actual output for the kwic method. If param table is TRUE, corpus positions will be turned into a data.frame with the concordance lines. If param s_attributes is a character vector with s-attributes, the respective s-attributes will be added as columns to the table with concordance lines.

The format-method will return a data.table that can serve as input for rendering a htmlwidget, for instance using DT::datatable or rhandsontable::rhandsontable. It will include html tags, so ensure that the rendering engine does not obfuscate the html.
Slots

- **metadata** A character vector with s-attributes of the metadata that are to be displayed.
- **p_attribute** The p-attribute for which the context has been generated.
- **left** An integer value, words to the left of the query match.
- **right** An integer value, words to the right of the query match.
- **corpus** Length-one character vector, the CWB corpus.
- **cpos** A data.table with the columns "match_id", "cpos", "position", "word_id", "word" and "direction".
- **stat** A data.table, a table with columns "left", "node", "right", and metadata, if the object has been enriched.
- **encoding** A length-one character vector with the encoding of the corpus.
- **name** A length-one character vector naming the object.
- **annotation_cols** A character vector designating the columns of the data.table in the slot that are annotations.

See Also

The constructor for generating kwic objects is the `kwic` method.

Examples

```r
use("polmineR")
K <- kwic("GERMAPARLMINI", "Integration")
get_corpus(K)
length(K)
K_min <- K[1]
K_min <- K[1:5]

# using kwic_bundle class
queries <- c("oil", "prices", "barrel")
li <- lapply(queries, function(q) kwic("REUTERS", query = q))
kb <- as.bundle(li)

# use count-method on kwic object
coi <- kwic("REUTERS", query = "oil") %>%
  count(p_attribute = "word")

# features vs cooccurrences-method (identical results)
ref <- count("REUTERS", p_attribute = "word") %>%
  subset(word != "oil")
slot(ref, "size") <- slot(ref, "size") - count("REUTERS", "oil")[["count"]]
y_features <- features(coi, ref, method = "ll", included = TRUE)
y_cococ <- cooccurrences("REUTERS", query = "oil")

# extract node and left and right context as character vectors
oil <- kwic("REUTERS", query = "oil")
as.character(oil, fmt = NULL)
as.character(oil) # node wrapped into <i> tag by default
```
as.character(oil, fmt = "<b>%s</b>")

# subsetting kwic objects
oil <- corpus("REUTERS") %>%
  kwic(query = "oil") %>%
  subset(grepl("prices", right))
saudi_arabia <- corpus("REUTERS") %>%
  kwic(query = "Arabia") %>%
  subset(grepl("Saudi", left))
int_spd <- corpus("GERMAPARLMINI") %>%
  kwic(query = "Integration") %>%
  enrich(s_attribute = "party") %>%
  subset(grepl("SPD", party))

# turn kwic object into data.frame with html tags
int <- corpus("GERMAPARLMINI") %>%
  kwic(query = "Integration")
as.data.frame(int) # Without further metadata
enrich(int, s_attributes = c("date", "speaker", "party")) %>%
as.data.frame()

# merge bundle of kwic objects into one kwic
reuters <- corpus("REUTERS")
queries <- c("Saudi" "Arabia", "oil", "barrel.*")
comb <- lapply(queries, function(qu) kwic(reuters, query = qu)) %>%
as.bundle() %>%
merge()

# enrich kwic object
i <- corpus("GERMAPARLMINI") %>%
  kwic(query = "Integration") %>%
enrich(s_attributes = c("date", "speaker", "party"))

---

**Compute Log-likelihood Statistics.**

**Description**

Apply the log-likelihood statistic to detect cooccurrences or keywords.

**Usage**

```r
ll(.Object, ...) # S4 method for signature 'features'
ll(.Object) # S4 method for signature 'context'
```
ll(.Object)

## S4 method for signature 'cooccurrences'
ll(.Object)

## S4 method for signature 'Cooccurrences'
ll(.Object, verbose = TRUE)

### Arguments

- **.Object**: An object of class `cooccurrence`, `context`, or `features`.
- **...**: Further arguments (such as `verbose`).
- **verbose**: Logical, whether to output messages.

### Details

The log-likelihood test to detect cooccurrences is a standard approach to find collocations (Dunning 1993, Evert 2005, 2009).

(a) The basis for computing for the log-likelihood statistic is a contingency table of observationes, which is prepared for every single token in the corpus. It reports counts for a token to inspect and all other tokens in a corpus of interest (coi) and a reference corpus (ref):

<table>
<thead>
<tr>
<th></th>
<th>coi</th>
<th>ref</th>
<th>TOTAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>count token</td>
<td>o₁₁</td>
<td>o₁₂</td>
<td>r₁</td>
</tr>
<tr>
<td>other tokens</td>
<td>o₂₁</td>
<td>o₂₂</td>
<td>r₂</td>
</tr>
<tr>
<td>TOTAL</td>
<td>c₁</td>
<td>c₂</td>
<td>N</td>
</tr>
</tbody>
</table>

(b) Based on the contingency table(s) with observed counts, expected values are calculated for each cell, as the product of the column and margin sums, divided by the overall number of tokens (see example).

(c) The standard formula for calculating the log-likelihood test is as follows.

\[
G^2 = 2 \sum_{ij} O_{ij} \log \left( \frac{O_{ij}}{E_{ij}} \right)
\]

Note: Before polmineR v0.7.11, a simplification of the formula was used (Rayson/Garside 2000), which omits the third and fourth term of the previous formula:

\[
ll = 2(o_{11} \log \left( \frac{o_{11}}{E_{11}} \right) + o_{12} \log \left( \frac{o_{12}}{E_{12}} \right))
\]

There is a (small) gain of computational efficiency using this simplified formula and the result is almost identical with the standard formula; see however the critical discussion of Ulrike Tabbert (2015: 84ff).

The implementation in the ll-method uses a vectorized approach of the computation, which is substantially faster than iterating the rows of a table, generating individual contingency tables etc. As using the standard formula is not significantly slower than relying on the simplified formula, polmineR has moved to the standard computation.
An inherent difficulty of the log likelihood statistic is that it is not possible to compute the statistical test value if the number of observed counts in the reference corpus is 0, i.e. if a term only occurs exclusively in the neighborhood of a node word. When filtering out rare words from the result table, respective NA values will usually disappear.

### means

**Description**

calculate means
Usage

`means(.Object, ...)`

## S4 method for signature 'DocumentTermMatrix'
`means(.Object, dim = 1)`

Arguments

- `.Object` object to work on
- `...` further parameters @exportMethod means
- `dim` numeric, 1 or 2 whether to work on rows or columns

---

ngrams

**Get N-Grams**

Description

Count n-grams, either of words, or of characters.

Usage

`ngrams(.Object, ...)`

## S4 method for signature 'partition'
`ngrams(
  .Object,
  n = 2,
  p_attribute = "word",
  char = NULL,
  progress = FALSE,

## S4 method for signature 'character'
ngrams(
  .Object,
n = 2,
p_attribute = "word",
char = NULL,
progress = FALSE,
  ...
)

## S4 method for signature 'data.table'
ngrams(.Object, n = 2L, p_attribute = "word")

## S4 method for signature 'corpus'
ngrams(
  .Object,
n = 2,
p_attribute = "word",
char = NULL,
progress = FALSE,
  ...
)

## S4 method for signature 'partition_bundle'
ngrams(
  .Object,
n = 2,
char = NULL,
p_attribute = "word",
m = FALSE,
progress = FALSE,)
...  

Arguments

- **Object** object of class partition
- Further arguments.
- **n** number of tokens/characters
- **p_attribute** the p-attribute to use (can be > 1)
- **char** If NULL, tokens will be counted, else characters, keeping only those provided by a character vector
- **progress** logical
- **mc** A logical value, whether to use multicore, passed into call to blapply (see respective documentation)

Examples

```r
use("polmineR")
P <- partition("GERMAPARLMINI", date = "2009-10-27")
ngramObject <- ngrams(P, n = 2, p_attribute = "word", char = NULL)

# a more complex scenario: get most frequent ADJA/NN-combinations
ngramObject <- ngrams(P, n = 2, p_attribute = c("word", "pos"), char = NULL)
ngramObject2 <- subset(ngramObject,
  ngramObject[['1_pos']] == "ADJA" & ngramObject[['2_pos']] == "NN" )
ngramObject2$stat[, "1_pos" := NULL][, "2_pos" := NULL]
ngramObject3 <- sort(ngramObject2, by = "count")
head(ngramObject3)

use("polmineR")
dt <- decode("REUTERS", p_attribute = "word", s_attribute = character(), to = "data.table")
y <- ngrams(dt, n = 3L, p_attribute = "word")
```

---

**ngrams_class**  
Ngrams class.

Description

Ngrams class.
Description

detect noise

Usage

noise(.Object, ...)

## S4 method for signature 'DocumentTermMatrix'
noise(.Object,
       minTotal = 2,
       minTfIdfMean = 0.005,
       sparse = 0.995,
       stopwordsLanguage = "german",
       minNchar = 2,
       specialChars = getOption("polmineR.specialChars"),
       numbers = "^[0-9\.,]+$",
       verbose = TRUE)

## S4 method for signature 'TermDocumentMatrix'
noise(.Object, ...)

## S4 method for signature 'character'
noise(.Object,
       stopwordsLanguage = "german",
       minNchar = 2,
       specialChars = getOption("polmineR.specialChars"),
       numbers = "^[0-9\.,]+$",
       verbose = TRUE)

## S4 method for signature 'textstat'
noise(.Object, p_attribute, ...)

Arguments

/Object/ an Object of class "DocumentTermMatrix"
... further parameters
/minTotal/ minimum colsum (for DocumentTermMatrix) to qualify a term as non-noise
/minTfIdfMean/ minimum mean value for tf-idf to qualify a term as non-noise
sparse will be passed into "removeSparseTerms" from "tm"-package

stopwordsLanguage e.g. "german", to get stopwords defined in the tm package

minNchar min char length to qualify a term as non-noise

specialChars special characters to drop

numbers regex, to drop numbers

verbose logical

p_attribute relevant if applied to a textstat object

Value

a list

ocpu_exec

Execute code on OpenCPU server

Description

ocpu_exec will execute a function/method fn on an OpenCPU server (specified by argument server), using three dots (...) to pass arguments. It is the worker of methods defined for remote_corpus, remote_subcorpus and remote_partition objects.

Usage

ocpu_exec(fn, corpus, server, restricted = FALSE, do.call = FALSE, ...)

Arguments

fn Name of the function/method to execute on remote server (length-one character vector).

corpus A length-one character vector, the id of the corpus to be queried.

server The IP/URL of the remote OpenCPU server.

restricted A logical value, whether credentials are required to access the data.

do.call Logical, if TRUE, the function fn is passed into a call of do.call, which offers some flexibility.

... Arguments passed into the method/function call.
Examples

```r
## Not run:
# Get polmineR version installed on remote server
ocpu_exec(
  fn = "packageVersion",
  server = Sys.getenv("OPENCPU_SERVER"),
  do.call = TRUE,
  pkg = "polmineR"
)

## End(Not run)
```

---

### partition

**Initialize a partition.**

**Description**

Create a subcorpus and keep it in an object of the `partition` class. If defined, counts are performed for the `p_attribute` defined by the parameter `p_attribute`.

**Usage**

```r
partition(.Object, ...)
```

**S4 method for signature 'character'**

```r
partition(
  .Object,
  def = NULL,
  name = "",
  encoding = NULL,
  p_attribute = NULL,
  regex = FALSE,
  xml = "flat",
  decode = TRUE,
  type = get_type(.Object),
  mc = FALSE,
  verbose = TRUE,
  ...
)
```

**S4 method for signature 'environment'**

```r
partition(.Object, slots = c("name", "corpus", "size", "p_attribute"))
```

**S4 method for signature 'partition'**

```r
partition(
  .Object,
  def = NULL,
  ...)
```
name = "", regex = FALSE, p_attribute = NULL, decode = TRUE, xml = NULL, verbose = TRUE, mc = FALSE, ...
)

## S4 method for signature 'context'
partition(.Object, node = TRUE)

## S4 method for signature 'remote_corpus'
partition(.Object, ...)

## S4 method for signature 'remote_partition'
partition(.Object, ...)

Arguments

/Object A length-one character-vector, the CWB corpus to be used.
... Arguments to define partition (see examples). If .Object is a remote_corpus or remote_partition object, the three dots (...) are used to pass arguments. Hence, it is necessary to state the names of all arguments to be passed explicitly.
def A named list of character vectors of s-attribute values, the names are the s-attributes (see details and examples)
name A name for the new partition object, defaults to "".
encoding The encoding of the corpus (typically "LATIN1 or "(UTF-8)), if NULL, the encoding provided in the registry file of the corpus (charset="...") will be used.
p_attribute The p-attribute(s) for which a count is performed.
regex A logical value (defaults to FALSE).
xml Either 'flat' (default) or 'nested'.
decode Logical, whether to turn token ids to strings (set FALSE to minimize object size / memory consumption) in data.table with counts.
type A length-one character vector specifying the type of corpus / partition (e.g. "plpr")
mc Whether to use multicore (for counting terms).
verbose Logical, whether to be verbose.
slots Object slots that will be reported columns of data.frame summarizing partition objects in environment.
node A logical value, whether to include the node (i.e. query matches) in the region matrix generated when creating a partition from a context-object.
Details

The function sets up a partition object based on s-attribute values. The s-attributes defining the partition can be passed in as a list, e.g. `list(interjection="speech",year = "2013")`, or directly (see examples).

The s-attribute values defining the partition may use regular expressions. To use regular expressions, set the parameter `regex` to `TRUE`. Regular expressions are passed into `grep`, i.e. the regex syntax used in R needs to be used (double backslashes etc.). If `regex` is `FALSE`, the length of the character vectors can be > 1, matching s-attributes are identifies with the operator '.

The XML imported into the CWB may be "flat" or "nested". This needs to be indicated with the parameter `xml` (default is "flat"). If you generate a partition based on a flat XML structure, some performance gain may be achieved when ordering the s-attributes with decreasingly restrictive conditions. If you have a nested XML, it is mandatory that the order of the s-attributes provided reflects the hierarchy of the XML: The top-level elements need to be positioned at the beginning of the list with the s-attributes, the the most restrictive elements at the end.

If `p_attribute` is not NULL, a count of tokens in the corpus will be performed and kept in the stat-slot of the partition-object. The length of the `p_attribute` character vector may be 1 or more. If two or more `p_attribute` are provided, The occurrence of combinations will be counted. A typical scenario is to combine the `p_attribute` "word" or "lemma" and "pos".

If `.Object` is a length-one character vector, a subcorpus/partition for the corpus defined be `.Object` is generated.

If `.Object` is an environment (typically `.GlobalEnv`), the partition objects present in the environment are listed.

If `.Object` is a partition object, a subcorpus of the subcorpus is generated.

Value

An object of the S4 class `partition`.

Author(s)

Andreas Blaette

See Also

To learn about the methods available for objects of the class `partition`, see `partition_class`.

Examples

```r
use("polmineR")
spd <- partition("GERMAPARLMINI", party = "SPD", interjection = "speech")
kauder <- partition("GERMAPARLMINI", speaker = "Volker Kauder", p_attribute = "word")
merkel <- partition("GERMAPARLMINI", speaker = ".*Merkel", p_attribute = "word", regex = TRUE)
s_attributes(merkel, "date")
s_attributes(merkel, "speaker")
merkel <- partition(
 "GERMAPARLMINI", speaker = "Angela Dorothea Merkel",
 date = "2009-11-10", interjection = "speech", p_attribute = "word"
)
```
merkel <- subset(merkel, !word %in% punctuation)
merkel <- subset(merkel, !word %in% tm::stopwords("de"))

# a certain defined time segment
days <- seq(
  from = as.Date("2009-10-28"),
  to = as.Date("2009-11-11"),
  by = "1 day"
)
period <- partition("GERMAPARLMINI", date = days)

---

**partition_bundle**

*Generate bundle of partitions.*

**Description**

Use `partition_bundle` to create a `partition_bundle` object, which combines a set of partition objects.

**Usage**

```r
partition_bundle(.Object, ...)
```

## S4 method for signature 'partition'
```r
partition_bundle(
  .Object,
  s_attribute,
  values = NULL,
  prefix = "",
  mc = getOption("polmineR.mc"),
  verbose = TRUE,
  progress = FALSE,
  type = get_type(.Object),
  ...
)
```

## S4 method for signature 'corpus'
```r
partition_bundle(
  .Object,
  s_attribute,
  values = NULL,
  prefix = "",
  mc = getOption("polmineR.mc"),
  verbose = TRUE,
  progress = FALSE,
  xml = "flat",
  type = get_type(.Object),
  ...
)
```
## S4 method for signature 'character'

```r
partition_bundle(
  .Object,
  s_attribute,
  values = NULL,
  prefix = "",
  mc = getOption("polmineR.mc"),
  verbose = TRUE,
  progress = FALSE,
  xml = "flat",
  type = get_type(.Object),
  ...
)
```

## S4 method for signature 'context'

```r
partition_bundle(.Object, node = TRUE, progress = TRUE, mc = 1L)
```

## S4 method for signature 'partition_bundle'

```r
partition_bundle(
  .Object,
  s_attribute,
  prefix = character(),
  progress = TRUE,
  mc = getOption("polmineR.mc")
)
```

**Arguments**

- `.Object`: A partition, a length-one character vector supplying a CWB corpus, or a `partition_bundle`
- `...`: parameters to be passed into partition-method (see respective documentation)
- `s_attribute`: The s-attribute to vary.
- `values`: Values the s-attribute provided shall assume.
- `prefix`: A character vector that will be attached as a prefix to partition names.
- `mc`: Logical, whether to use multicore parallelization.
- `verbose`: Logical, whether to provide progress information.
- `progress`: Logical, whether to show progress bar.
- `type`: The type of partition to generate.
- `xml`: A logical value.
- `node`: A logical value, whether to include the node (i.e. query matches) in the region matrix generated when creating a partition from a context-object.
Details

Applying the partition_bundle-method to a partition_bundle-object will iterate through the partition objects in the object-slot in the partition_bundle, and apply partition_bundle on each partition, splitting it up by the s-attribute provided by the argument s_attribute. The return value is a partition_bundle, the names of which will be the names of the incoming partition_bundle concatenated with the s-attribute values used for splitting. The argument prefix can be used to achieve a more descriptive name.

Value

S4 class partition_bundle, with list of partition objects in slot 'objects'

Author(s)

Andreas Blaette

See Also

partition and bundle

Examples

```r
use("polmineR")
bt2009 <- partition("GERMAPARLMINI", date = "2009-.*", regex = TRUE)
pb <- partition_bundle(bt2009, s_attribute = "date", progress = TRUE)
pb <- enrich(pb, p_attribute = "word")
dtm <- as.DocumentTermMatrix(pb, col = "count")
summary(pb)
pb <- partition_bundle("GERMAPARLMINI", s_attribute = "date")
# split up objects in partition_bundle by using partition_bundle-method
use("polmineR")
pb <- partition_bundle("GERMAPARLMINI", s_attribute = "date")
pb2 <- partition_bundle(pb, s_attribute = "speaker", progress = FALSE)
summary(pb2)
```

partition_bundle-class

Bundle of partitions (partition_bundle class).

Description

Class and methods to manage bundles of partitions.
Usage

```r
## S4 method for signature 'partition_bundle'
show(object)

## S4 method for signature 'partition_bundle'
summary(object, progress = FALSE)

## S4 method for signature 'partition_bundle'
merge(x, name = "", verbose = FALSE)

## S4 method for signature 'partition_bundle,ANY,ANY,ANY'
x[i]

## S4 method for signature 'partition_bundle'
barplot(height, ...)

## S4 method for signature 'list'
as.partition_bundle(.Object, ...)

## S4 method for signature 'environment'
partition_bundle(.Object)

## S4 method for signature 'partition_bundle'
enrich(.Object, mc = FALSE, progress = TRUE, verbose = FALSE, ...)

## S4 method for signature 'partition_bundle'
s_attributes(.Object, s_attribute, ...)

flatten(object)
```

Arguments

- `object` a partition_bundle object
- `progress` logical
- `x` a partition_bundle object
- `name` the name for the new partition
- `verbose` logical
- `i` integer index
- `height` height
- `...` further parameters
- `.Object` a partition_bundle object
- `mc` logical or, if numeric, providing the number of cores
- `s_attribute` the s-attribute to use
Details

The `merge`-method aggregates several partitions into one partition. The prerequisite for this function to work properly is that there are no overlaps of the different partitions that are to be summarized. Encodings and the root node need to be identical, too.

Using brackets can be used to retrieve the count for a token from the partition objects in a `partition_bundle`.

Value

An object of the class `partition`. See `partition` for the details on the class.

A `partition_bundle` object

Slots

- `objects` Object of class `list` the partitions making up the bundle
- `corpus` Object of class `character` the CWB corpus the partition is based on
- `s_attributes_fixed` Object of class `list` fixed s-attributes
- `encoding` Object of class `character` encoding of the corpus
- `explanation` Object of class `character` an explanation of the partition
- `xml` Object of class `character` whether the xml is flat or nested
- `call` Object of class `character` the call that generated the `partition_bundle`

Author(s)

Andreas Blaette

Examples

```r
# merge partition_bundle into one partition
gparl <- corpus("GERMAPARLMINI")  %>%
   split(s_attribute = "date")  %>%
   merge()
pb <- partition_bundle("REUTERS", s_attribute = "id")
barplot(pb, las = 2)

sc <- corpus("GERMAPARLMINI")  %>%
   subset(date == "2009-11-10")  %>%
   split(s_attribute = "speaker")  %>%
   barplot(las = 2)
```
Description

The partition class is used to manage subcorpora. It is an S4 class, and a set of methods is defined for the class. The class inherits from the classes count and textstat.

Usage

```r
## S4 method for signature 'partition'
p_attributes(.Object, p_attribute = NULL, decode = TRUE)

## S4 method for signature 'subcorpus'
p_attributes(.Object, p_attribute = NULL, decode = TRUE)

is.partition(x)

## S4 method for signature 'partition'
enrich(
  .Object,
  p_attribute = NULL,
  decode = TRUE,
  verbose = TRUE,
  mc = FALSE,
  ...
)

## S4 method for signature 'partition'
as.regions(x)

## S4 method for signature 'partition'
split(x, gap, ...)
```

Arguments

- `.Object` A partition object.
- `p_attribute` a p-attribute (for enriching) / performing count.
- `decode` logical value, whether to decode token ids into strings when performing count.
- `x` A partition object.
- `verbose` logical value, whether to output messages.
- `mc` logical or, if numeric, providing the number of cores.
- `...` further parameters passed into count when calling enrich, and ...
- `gap` An integer value specifying the minimum gap between regions for performing the split.
Details

As partition objects inherit from count and textstat class, methods available are view to inspect the table in the stat slot, name and name<- to retrieve/set the name of an object, and more.

The is.partition function returns a logical value whether x is a partition, or not.

The enrich-method will add a count of tokens defined by argument p_attribute to slot stat of the partition object.

The split-method will split a partition object into a partition_bundle if gap between struc exceeds a minimum number of tokens specified by gap. Relevant to split up a plenary protocol into speeches. Note: To speed things up, the returned partitions will not include frequency lists. The lists can be prepared by applying enrich on the partition_bundle object that is returned.

Slots

name  A name to identify the object (character vector with length 1); useful when multiple partition objects are combined to a partition_bundle.
corpus  The CWB indexed corpus the partition is derived from (character vector with length 1).
encoding  Encoding of the corpus (character vector with length 1).
s_attributes  A named list with the s-attributes specifying the partition.
explanation  Object of class character, an explanation of the partition.
cpos  A matrix with left and right corpus positions defining regions (two columns).
annotations  Object of class list.
size  Total size of the partition (integer vector, length 1).
stat  An (optional) data.table with counts. If present, speeds up computation of cooccurrences, as count is already present.
metadata  Object of class data.frame, metadata information.
strucs  Object of class integer, the strucs defining the partition.
p_attribute  Object of class character indicating the p_attribute of the count in slot stat.
xml  Object of class character, whether the xml is flat or nested.
s_attribute_strucs  Object of class character the base node key  Experimental, an s-attribute that is used as a key.
call  Object of class character the call that generated the partition

Author(s)

Andreas Blaette

See Also

The partition-class inherits from the textstat-class, see respective documentation to learn more.
Examples

```r
p <- partition(“GERMAPARLMINI”, date = “2009-11-11”, speaker = “Norbert Lammert”)
name(p) <- “Norbert Lammert”
pb <- split(p, gap = 500L)
summary(pb)
```

Description

Decode as String.

Examples

```r
use(“polmineR”)  
p <- partition(“GERMAPARLMINI”, date = “2009-11-10”, speaker = “Angela Dorothea Merkel”)
s <- as(p, “String”)  
```

phrases

Manage and use phrases

Description

Class, methods and functionality for processing phrases (lexical units, lexical items, multi-word expressions) beyond the token level. The envisaged workflow at this stage is to detect phrases using the ngrams-method and to generate a phrases class object from the ngrams object using the as.phrases method. This object can be passed into a call of count, see examples. Further methods and functions documented here are used internally, but may be useful.

Usage

```r
## S4 method for signature 'ngrams'
as.phrases(.Object, …)

## S4 method for signature 'matrix'
as.phrases(.Object, corpus, enc = encoding(corpus))

## S4 method for signature 'phrases'
as.character(x, p_attribute)
concatenate_phrases(dt, phrases, col)
```
Arguments

- **.Object**: Input object, either a `ngrams` or a `matrix` object.
- **corpus**: A length-one character vector, the corpus ID of the corpus from which regions / the `data.table` representing a decoded corpus is derived.
- **enc**: Encoding of the corpus.
- **x**: A `phrases` class object.
- **p_attribute**: The positional attribute (p-attribute) to decode.
- **dt**: A `data.table`.
- **phrases**: A `phrases` class object.
- **col**: If `.Object` is a `data.table`, the column to concatenate.

Details

The `phrases` considers a phrase as sequence as tokens that can be defined by region, i.e. a left and a right corpus position. This information is kept in a region matrix in the slot "cpos" of the `phrases` class. The `phrases` class inherits from the `regions` class (which inherits from the and the `corpus` class), without adding further slots.

If `.Object` is an object of class `ngrams`, the `as.phrases-method` will interpret the ngrams as CQP queries, look up the matching corpus positions and return an `phrases` object.

If `.Object` is a `matrix`, the `as.phrases-method` will initialize a `phrases` object. The corpus and the encoding of the corpus will be assigned to the object.

Applying the `as.character-method` on a `phrases` object will return the decoded regions, concatenated using an underscore as separator.

The `concatenate_phrases` function takes a `data.table` (argument `dt`) as input and concatenates phrases in successive rows into a phrase.

Other classes to manage corpora: `corpus-class`, `regions`, `subcorpus`

Examples

```r
# Workflow to create document-term-matrix with phrases
obs <- corpus("GERMAPARLMINI") %>%
  count(p_attribute = "word")

phrases <- corpus("GERMAPARLMINI") %>%
  ngrams(n = 2L, p_attribute = "word") %>%
  pmi(observed = obs) %>%
  subset(ngram_count > 5L) %>%
  subset(1:100) %>%
  as.phrases()

dtm <- corpus("GERMAPARLMINI") %>%
```

```
as.speeches(s_attribute_name = "speaker", progress = TRUE) %>%
count(phrases = phrases, p_attribute = "word", progress = TRUE, verbose = TRUE) %>%
as.DocumentTermMatrix(col = "count", verbose = FALSE)

grep("erneuerbaren_Energien", colnames(dtm))
grep("verpasste_Chancen", colnames(dtm))

# Derive phrases object from an ngrams object

reuters_phrases <- ngrams("REUTERS", p_attribute = "word", n = 2L) %>%
  pmi(observed = count("REUTERS", p_attribute = "word")) %>%
  subset(ngram_count >= 5L) %>%
  subset(1:25) %>%
  as.phrases()

phr <- as.character(reuters_phrases, p_attribute = "word")

# Derive phrases from explicitly stated CQP queries

cqp_phrase_queries <- c("oil" "revenue";",
"Sheikh" "Aziz";",
"Abdul" "Aziz";",
"Saudi" "Arabia";",
"oil" "markets";
) reuters_phrases <- cpos("REUTERS", cqp_phrase_queries, p_attribute = "word") %>%
  as.phrases(corpus = "REUTERS", enc = "latin1")

# Use the concatenate_phrases() function on a data.table

lexical_units_cqp <- c("Deutsche.*" "Bundestag.*";",
"sozial.*" "Gerechtigkeit";",
"Ausschuss" "f.r" "Arbeit" "und" "Soziales";",
"soziale.*" "Marktwirtschaft";",
"freiheitliche.*" "Grundordnung";
)

phr <- cpos("GERMAPARLMINI", query = lexical_units_cqp, cqp = TRUE) %>%
  as.phrases(corpus = "GERMAPARLMINI", enc = "word")

dt <- corpus("GERMAPARLMINI") %>%
decode(p_attribute = "word", s_attribute = character(), to = "data.table") %>%
concatenate_phrases(phrases = phr, col = "word")
dt[word == "Deutschen_Bundestag"]
dt[word == "soziale_Marktwirtschaft"]

Calculate Pointwise Mutual Information (PMI).
Description

Calculate Pointwise Mutual Information as an information-theoretic approach to find collocations.

Usage

`pmi(.Object, ...)`

```r
## S4 method for signature 'context'
pmi(.Object)
```

```r
## S4 method for signature 'Cooccurrences'
pmi(.Object)
```

```r
## S4 method for signature 'ngrams'
pmi(.Object, observed, p_attribute = p_attributes(.Object)[1])
```

Arguments

- `...`: Arguments methods may require.
- `observed`: A count-object with the numbers of the observed occurrences of the tokens in the input ngrams object.
- `p_attribute`: The positional attribute which shall be considered. Relevant only if ngrams have been calculated for more than one p-attribute.

Details

Pointwise mutual information (PMI) is calculated as follows (see Manning/Schuetze 1999):

$$I(x, y) = \log \frac{p(x, y)}{p(x)p(y)}$$

The formula is based on maximum likelihood estimates: When we know the number of observations for token x, \(o_x\), the number of observations for token y, \(o_y\) and the size of the corpus N, the probabilities for the tokens x and y, and for the co-occurrence of x and y are as follows:

$$p(x) = \frac{o_x}{N}$$

$$p(y) = \frac{o_y}{N}$$

The term \(p(x, y)\) is the number of observed co-occurrences of x and y.

Note that the computation uses log base 2, not the natural logarithm you find in examples (e.g. https://en.wikipedia.org/wiki/Pointwise_mutual_information).

obs <- count("REUTERS", p_attribute = "word")
phrases <- pmi(n, observed = obs)
\end{verbatim}
Description

This documentation object gives an overview over the generic methods defined in the polmineR package that have no individual man page but are documented directly with the classes they are defined for.

Usage

\begin{verbatim}
get_info(x)
show_info(x)
\end{verbatim}

Arguments

\begin{verbatim}
x
\end{verbatim}

An S4 class object.

p_attributes

Get p-attributes.

Description

In a CWB corpus, every token has positional attributes. While s-attributes cover a range of tokens, every single token in the token stream of a corpus will have a set of positional attributes (such as part-of-speech, or lemma). The available p-attributes are returned by the \texttt{p_attributes}-method.

Usage

\begin{verbatim}
p_attributes(.Object, ...)
\end{verbatim}

\begin{verbatim}
## S4 method for signature 'character'
p_attributes(.Object, p_attribute = NULL)
\end{verbatim}

\begin{verbatim}
## S4 method for signature 'corpus'
p_attributes(.Object, p_attribute = NULL)
\end{verbatim}

\begin{verbatim}
## S4 method for signature 'slice'
p_attributes(.Object, p_attribute = NULL, decode = TRUE)
\end{verbatim}

\begin{verbatim}
## S4 method for signature 'partition_bundle'
p_attributes(.Object, p_attribute = NULL, decode = TRUE)
\end{verbatim}
Arguments

.plot.A Object
A length-one character vector, or a partition object.

.plot.A ...
Arguments passed to get_token_stream.

.plot.A p_attribute
A p-attribute to decode, provided by a length-one character vector.

.plot.A decode
A length-one logical value. Whether to return decoded p-attributes or unique token ids.

Details

The p_attributes-method returns the p-attributes defined for the corpus the partition is derived from, if argument p_attribute is NULL (the default). If p_attribute is defined, the unique values for the p-attribute are returned.

References

Examples

use("polmineR")
p_attributes("GERMAPARLMINI")
p_attributes("REUTERS")
p_attributes("REUTERS", p_attribute = "word")

Description

Generate text (i.e. html) and display it in the viewer pane of RStudio for reading it. If called on a partition_bundle-object, skip through the partitions contained in the bundle.

Usage

read(.Object, ...)

## S4 method for signature 'partition'
read(
  .Object,
  meta = NULL,
  highlight = list(),
  tooltips = list(),
  verbose = TRUE,
  cpos = TRUE,
  cutoff = getOption("polmineR.cutoff"),
  template = get_template(.Object),
)
## S4 method for signature 'subcorpus'
read(
  .Object,
  meta = NULL,
  highlight = list(),
  tooltips = list(),
  verbose = TRUE,
  cpos = TRUE,
  cutoff = getOption("polmineR.cutoff"),
  template = get_template(.Object),
...
)

## S4 method for signature 'partition_bundle'
read(.Object, highlight = list(), cpos = TRUE, ...)

## S4 method for signature 'data.table'
read(.Object, col, partition_bundle, highlight = list(), cpos = FALSE, ...)

## S4 method for signature 'hits'
read(.Object, def, i = NULL, ...)

## S4 method for signature 'kwic'
read(.Object, i = NULL, type)

## S4 method for signature 'regions'
read(.Object, meta = NULL)

### Arguments

- `.Object` an object to be read (partition or partition_bundle)
- `...` further parameters passed into read
- `meta` a character vector supplying s-attributes for the metainformation to be printed; if not stated explicitly, session settings will be used
- `highlight` a named list of character vectors (see details)
- `tooltips` a named list (names are colors, vectors are tooltips)
- `verbose` logical
- `cpos` logical, if TRUE, corpus positions will be assigned (invisibly) to a cpos tag of a html element surrounding the tokens
- `cutoff` maximum number of tokens to display
- `template` template to format output
- `col` column of data.table with terms to be highlighted
**partition_bundle**

a partition_bundle object

**def**

a named list used to define a partition (names are s-attributes, vectors are values of s-attributes)

**i**

if .Object is an object of the classes kwic or hits, the ith kwic line or hit to derive a partition to be inspected from

**type**

the partition type, see documentation for partition-method

---

**Details**

To prepare the html output, the method read will call html and as.markdown subsequently, the latter method being the actual worker. Consult these methods to understand how preparing the output works.

The param highlight can be used to highlight terms. It is expected to be a named list of character vectors, the names providing the colors, and the vectors the terms to be highlighted. To add tooltips, use the param tooltips.

The method read is a high-level function that calls the methods mentioned before. Results obtained through read can also be obtained through combining these methods in a pipe using the package magrittr. That may offer more flexibility, e.g. to highlight matches for CQP queries. See examples and the documentation for the different methods to learn more.

---

**See Also**

For concordances / a keyword-in-context display, see **kwic**.

---

**Examples**

```r
use("polmineR")
merkel <- partition("GERMAPARLMINI", date = "2009-11-10", speaker = "Merkel", regex = TRUE)
if (interactive()) read(merkel, meta = c("speaker", "date"))
if (interactive()) read(
  merkel,
  highlight = list(yellow = c("Deutschland", "Bundesrepublik"), lightgreen = "Regierung"),
  meta = c("speaker", "date")
)
## Not run:
pb <- as.speeches("GERMAPARLMINI", s_attribute_date = "date", s_attribute_name = "speaker")
pb <- pb[[ data.table::as.data.table(summary(pb))[size >= 500][["name"]]]]
pb <- pb[[1:10]]
read(pb)
## End(Not run)
```
Description

A coerce-method is available to coerce a partition object to a regions object.

Usage

\[
\text{as.regions}(x, \ldots)
\]

## S3 method for class 'regions'
\[
\text{as.data.table}(x, \text{keep.rownames}, \text{values} = \text{NULL}, \ldots)
\]

Arguments

- **x**: object of class regions
- **...**: Further arguments.
- **keep.rownames**: Required argument to safeguard consistency with S3 method definition in the data.table package. Unused in this context.
- **values**: values to assign to a column that will be added

Details

The virtual class CorpusOrSubcorpus is a way to handle corpora specified by a character vector, region objects, and partition objects in a uniform manner.

The as.regions-method coerces objects to a regions-object.

The as.data.table method returns the matrix with corpus positions in the slot cpos as a data.table.

Slots

- **cpos**: a two-column data.table that will include a "cpos_left" and "cpos_right" column
- **corpus**: the CWB corpus (character vector length 1)
- **encoding**: the encoding of the CWB corpus (character vector length 1)

See Also

Other classes to manage corpora: corpus-class, phrases, subcorpus
Examples

```r
use("polmineR")
P <- partition("GERMAPARLMINI", date = "2009-11-12", speaker = "Jens Spahn")
R <- as.regions(P)

# Get regions matrix as data.table, without / with values
sc <- corpus("REUTERS") %>% subset(grep("saudi-arabia", places))
regions_dt <- as.data.table(sc)
regions_dt <- as.data.table(
    sc,
    values = s_attributes(sc, "id", unique = FALSE)
)
```

registry_get_name  Evaluate registry file.

Description

Functions to extract information from a registry file describing a corpus. Several operations could be accomplished with the 'cwb-regedit' tool, the functions defined here ensure that manipulating the registry is possible without a full installation of the CWB.

Usage

```r
registry_get_name(corpus, registry = Sys.getenv("CORPUS_REGISTRY"))
registry_get_id(corpus, registry = Sys.getenv("CORPUS_REGISTRY"))
registry_get_home(corpus, registry = Sys.getenv("CORPUS_REGISTRY"))
registry_get_info(corpus, registry = Sys.getenv("CORPUS_REGISTRY"))
registry_get_encoding(corpus, registry = Sys.getenv("CORPUS_REGISTRY"))
registry_get_p_attributes(corpus, registry = Sys.getenv("CORPUS_REGISTRY"))
registry_get_s_attributes(corpus, registry = Sys.getenv("CORPUS_REGISTRY"))
registry_get_properties(corpus, registry = Sys.getenv("CORPUS_REGISTRY"))
```

Arguments

- corpus: name of the CWB corpus
- registry: directory of the registry (defaults to CORPUS_REGISTRY environment variable)
Details

An appendix to the 'CorpusEncoding Tutorial' (http://cwb.sourceforge.net/files/CWB_Encoding_Tutorial.pdf) includes an explanation of the registry file format.

registry_get_encoding will parse the registry file for a corpus and return the encoding that is defined (corpus property "charset"). If parsing the registry does not yield a result (corpus property "charset" not defined), the CWB standard encoding ("latin1") is assigned to prevent errors. Note that RcppCWB::cl_charset_name is equivalent but is faster as it uses the internal C representation of a corpus rather than parsing the registry file.

Examples

registry_get_encoding("REUTERS")

registry_move

Get registry and data directories.

Description

The Corpus Workbench (CWB) uses a registry directory with plain text files describing corpora in a standardized format. The binary files of a corpus are stored in a data directory defined in the registry directory. The registry and data_dir functions return the respective directories within a package, if the argument pkg is used, or the temporary registry and data directory in the per-session temporary directory, if pkg is NULL (default value).

Usage

registry_move(corpus, registry, registry_new, home_dir_new)

registry(pkg = NULL)

data_dir(pkg = NULL)

Arguments

corpus The ID of the corpus for which the registry file shall be moved.
registry The old registry directory.
registry_new The new registry directory.
home_dir_new The new home directory.
pkg A character string with the name of a single package; if NULL (default), the temporary registry and data directory is returned.
**Details**

The registry_move is an auxiliary function to create a copy of a registry file in the directory specified by the argument registry_new.

Upon loading the polmineR package, there is a check whether the environment variable CORPUS_REGISTRY is defined. In case it is, the registry files in the directory defined by the CORPUS_REGISTRY environment variable are copied to the temporary registry directory, which serves as the central place to store all registry files for all corpora, be it system corpora, corpora included in R packages, or temporary corpora.

The Corpus Workbench may have problems to cope with a registry path that includes registry non-ASCII characters. On Windows, a call to utils::shortPathName will generate the short MS-DOS path name that circumvents resulting problems.

Usage of the temporary registry directory can be suppress by setting the environment variable POLMINER_USE_TMP_REGISTRY as 'false'. In this case, the registry function will return the environment variable CORPUS_REGISTRY unchanged. The data_dir function will return the "indexed_corpus" directory that is assumed to live in the same parent directory as the registry directory.

**Value**

A path to a (registry or data) directory, or NULL, if package does not exist or is not a package including a corpus.

**Examples**

```r
registry() # returns temporary registry directory
registry(pkg = "polmineR") # returns registry directory in polmineR-package

data_dir()
data_dir(pkg = "polmineR")
```

---

**registry_reset**

*Reset registry directory.*

**Description**

A utility function to reset the environment variable CORPUS_REGISTRY. That may be necessary if you want use a CWB corpus that is not stored in the usual place. In particular, resetting the environment variable is required if you want to use a corpus delivered in a R package.

**Usage**

```r
registry_reset(registryDir = registry(), verbose = TRUE)
```

**Arguments**

- `registryDir` path to the registry directory to be used
- `verbose` logical, whether to be verbose
Details

Resetting the CORPUS_REGISTRY environment variable is also necessary for the interface to CWB corpora.
To get the path to a package that contains a CWB corpus, use system.file (see examples).

Value

the registry directory used before resetting CORPUS_REGISTRY

See Also

To conveniently reset registry, see use.

Examples

```r
## Not run:
x <- system.file(package = "polmineR", "extdata", "cwb", "registry")
registry_reset(registryDir = x)
## End(Not run)
```

---

### Renamed Functions

**Description**

These functions have been renamed in order to have a consistent coding style that follows the snake_case convention. The "old" function still work to maintain backwards compatibility.

**Usage**

- `sAttributes(...)
- `pAttributes(...)
- `getTokenStream(...)
- `getTerms(...)
- `getEncoding(...)
- `partitionBundle(...)
- `as.partitionBundle(...)
- `## S4 method for signature 'textstat'
corpus(.Object)`
Arguments

... argument that are passed to the renamed function

.Object A kwic object.

Description

Reloading an S4 object that has a slot with a data.table may result in buggy behavior. This auxiliary function will copy the data.table once to have a restored object that works.

Usage

restore(filename)

Arguments

filename A *.rds file to restore.

Examples

k <- kwic("REUTERS", query = "oil")
kwicfile <- tempfile()
saveRDS(k, file = kwicfile)
k <- restore(filename = kwicfile)
k2 <- enrich(k, s_attribute = "id")
**size**

*Get Number of Tokens.*

**Description**

The method will get the number of tokens in a corpus or partition, or the dispersion across one or more s-attributes.

**Usage**

```r
size(x, ...)  # S4 method for signature 'corpus'
size(x, s_attribute = NULL, verbose = TRUE, ...)

## S4 method for signature 'character'
size(x, s_attribute = NULL, verbose = TRUE, ...)

## S4 method for signature 'partition'
size(x, s_attribute = NULL, ...)

## S4 method for signature 'partition_bundle'
size(x)

## S4 method for signature 'DocumentTermMatrix'
size(x)

## S4 method for signature 'TermDocumentMatrix'
size(x)

## S4 method for signature 'features'
size(x)

## S4 method for signature 'remote_corpus'
size(x)

## S4 method for signature 'remote_partition'
size(x)
```

**Arguments**

- `x`: An object to get size(s) for.
- `...`: Further arguments (used only for backwards compatibility).
- `s_attribute`: A character vector with s-attributes (one or more).
- `verbose`: A logical value, whether to output messages.
Details

One or more s-attributes can be provided to get the dispersion of tokens across one or more dimensions. Two or more s-attributes can lead to reasonable results only if the corpus XML is flat.

The size-method for features objects will return a named list with the size of the corpus of interest ("coi"), i.e. the number of tokens in the window, and the reference corpus ("ref"), i.e. the number of tokens that are not matched by the query and that are outside the window.

Value

If .Object is a corpus (a corpus object or specified by corpus id), an integer vector if argument s_attribute is NULL, a two-column data.table otherwise (first column is the s-attribute, second column: "size"). If .Object is a subcorpus_bundle or a partition_bundle, a data.table (with columns "name" and "size").

See Also

See dispersion-method for counts of hits. The hits method calls the size-method to get sizes of subcorpora.

Examples

use("polmineR")

# for corpus object
corpus("REUTERS") %>% size()
corpus("REUTERS") %>% size(s_attribute = "id")
corpus("GERMAPARLMINI") %>% size(s_attribute = c("date", "party"))

# for corpus specified by ID
size("GERMAPARLMINI")
size("GERMAPARLMINI", s_attribute = "date")
size("GERMAPARLMINI", s_attribute = c("date", "party"))

# for partition object
P <- partition("GERMAPARLMINI", date = "2009-11-11")
size(P, s.attribute = "speaker")
size(P, s.attribute = "party")
size(P, s.attribute = c("speaker", "party"))

# for subcorpus
sc <- corpus("GERMAPARLMINI") %>% subset(date == "2009-11-11")
size(sc, s.attribute = "speaker")
size(sc, s.attribute = "party")
size(sc, s.attribute = c("speaker", "party"))

# for subcorpus_bundle
subcorpora <- corpus("GERMAPARLMINI") %>% split(s.attribute = "date")
size(subcorpora)
slice  Virtual class slice.

Description
The classes subcorpus and partition can be used to define subcorpora. Unlike the subcorpus class, the partition class may include statistical evaluations. The virtual class slice is a mechanism to define methods for these classes without making subcorpus the superclass of partition.

Usage
```r
## S4 method for signature 'slice'
aggregate(x)
```

Arguments
- `x` An object of a class belonging to the virtual class slice, i.e. a partition or regions object.

Details
The method aggregate will deflate the matrix in the slot cpos, i.e. it checks for each new row in the matrix whether it increments the end of the previous region (by 1), and ensure that the cpos matrix defines disjoined regions.

Examples
```r
P <- new("partition",
    "cpos = matrix(data = c(1:10, 20:29), ncol = 2, byrow = TRUE),
    stat = data.table::data.table()
)
P2 <- aggregate(P)
P2@cpos
```

subcorpus  The S4 subcorpus class.

Description
Class to manage subcorpora derived from a CWB corpus.
subcorpus

Usage

```r
## S4 method for signature 'subcorpus'
summary(object)

## S4 replacement method for signature 'subcorpus'
name(x) <- value

## S4 method for signature 'subcorpus'
get_corpus(x)

## S4 method for signature 'subcorpus'
size(x, s_attribute = NULL, ...)
```

Arguments

- `object`: A subcorpus object.
- `x`: A subcorpus object.
- `value`: A character vector to assign as name to slot `name` of a subcorpus class object.
- `s_attribute`: A character vector with s-attributes (one or more).
- `...`: Arguments passed into `size`-method. Used only to maintain backwards compatibility.

Methods (by generic)

- `summary`: Get named list with basic information for subcorpus object.
- `name<-`: Assign name to a subcorpus object.
- `get_corpus`: Get the corpus ID from the subcorpus object.
- `size`: Get the size of a subcorpus object from the respective slot of the object.

Slots

- `s_attributes`: A named list with the structural attributes defining the subcorpus.
- `cpos`: A matrix with left and right corpus positions defining regions (two column matrix with integer values).
- `annotations`: Object of class list.
- `size`: Total size (number of tokens) of the subcorpus object (a length-one integer vector). The value is accessible by calling the `size`-method on the subcorpus-object (see examples).
- `metadata`: Object of class data.frame, metadata information.
- `strucs`: Object of class integer, the strucs defining the subcorpus.
- `xml`: Object of class character, whether the xml is "flat" or "nested".
- `s_attribute_strucs`: Object of class character, the base node.
- `user`: If the corpus on the server requires authentication, the username.
- `password`: If the corpus on the server requires authentication, the password.
subcorpus_bundle-class

See Also

Most commonly, a subcorpus is derived from a corpus or a subcorpus using the `subset` method. See `size` for detailed documentation on how to use the `size`-method. The subcorpus class shares many features with the partition class, but it is more parsimonious and does not include information on statistical properties of the subcorpus (i.e. a count table). In line with this logic, the subcorpus class inherits from the corpus class, whereas the partition class inherits from the `textstat` class.

Other classes to manage corpora: `corpus-class`, `phrases`, `regions`

Examples

```r
use("polmineR")

# basic example
r <- corpus("REUTERS")
k <- subset(r, grepl("kuwait", places))
name(k) <- "kuwait"
y <- summary(k)
s <- size(k)

# the same with a magrittr pipe
corpus("REUTERS") %>%
  subset(grepl("kuwait", places)) %>%
  summary()

# subsetting a subcorpus in a pipe
stone <- corpus("GERMAPARLMINI") %>%
  subset(date == "2009-11-10") %>%
  subset(speaker == "Frank-Walter Steinmeier")

# perform count for subcorpus
n <- corpus("REUTERS") %>%
  subset(grep("kuwait", places)) %>%
  count(p_attribute = "word")
n <- corpus("REUTERS") %>%
  subset(grep("saudi-arabia", places)) %>%
  count("Saudi" "Arabia")

# keyword-in-context analysis (kwic)
k <- corpus("REUTERS") %>%
  subset(grepl("kuwait", places)) %>%
  kwic("oil")
```

subcorpus_bundle-class

Bundled subcorpora

Description

A subcorpus_bundle object combines a set of subcorpus objects in a list in the the slot objects. The class inherits from the `partition_bundle` and the bundle class. Typically, a subcorpus_bundle is generated by applying the `split`-method on a corpus or subcorpus.
Usage

```r
## S4 method for signature 'subcorpus_bundle'
show(object)

## S4 method for signature 'subcorpus_bundle'
merge(x, name = "", verbose = FALSE)

## S4 method for signature 'subcorpus'
merge(x, y, ...)

## S4 method for signature 'subcorpus'
split(
  x,
  s_attribute,
  values = NULL,
  prefix = "",
  mc =getOption("polmineR.mc"),
  verbose = TRUE,
  progress = FALSE,
  type = get_type(x)
)

## S4 method for signature 'corpus'
split(
  x,
  s_attribute,
  values = NULL,
  prefix = "",
  mc =getOption("polmineR.mc"),
  verbose = TRUE,
  progress = FALSE,
  type = get_type(x),
  xml = "flat"
)

## S4 method for signature 'subcorpus_bundle'
split(
  x,
  s_attribute,
  prefix = "",
  progress = TRUE,
  mc = getOption("polmineR.mc")
)
```

Arguments

- `object` An object of class `subcorpus_bundle`.
- `x` A corpus, subcorpus, or `subcorpus_bundle` object.
name  The name of the new subcorpus object.
verbose Logical, whether to provide progress information.
y  A subcorpus to be merged with x.
...  Further subcorpus objects to be merged with x and y.
s_attribute  The s-attribute to vary.
values  Values the s-attribute provided shall assume.
prefix  A character vector that will be attached as a prefix to partition names.
mc Logical, whether to use multicore parallelization.
progress Logical, whether to show progress bar.
type  The type of partition to generate.
xml A logical value.

Details

Applying the split-method to a subcorpus_bundle-object will iterate through the subcorpus, and apply split on each subcorpus object in the bundle, splitting it up by the s-attribute provided by the argument s_attribute. The return value is a subcorpus_bundle, the names of which will be the names of the incoming partition_bundle concatenated with the s-attribute values used for splitting. The argument prefix can be used to achieve a more descriptive name.

Examples

```r
corpus("REUTERS") %>% split(s_attribute = "id") %>% summary()

# Merge multiple subcorpus objects
a <- corpus("GERMAPARLMINI") %>% subset(date == "2009-10-27")
b <- corpus("GERMAPARLMINI") %>% subset(date == "2009-10-28")
c <- corpus("GERMAPARLMINI") %>% subset(date == "2009-11-10")
y <- merge(a, b, c)
s_attributes(y, "date")
sc <- subset("GERMAPARLMINI", date == "2009-11-11")
b <- split(sc, s_attribute = "speaker")

p <- partition("GERMAPARLMINI", date = "2009-11-11")
y <- partition_bundle(p, s_attribute = "speaker")
gparl <- corpus("GERMAPARLMINI")
b <- split(gparl, s_attribute = "date")
# split up objects in partition_bundle by using partition_bundle-method
use("polmineR")
y <- corpus("GERMAPARLMINI") %>%
  split(s_attribute = "date") %>%
  split(s_attribute = "speaker")

summary(y)
```
subset

Subsetting corpora and subcorpora

Description
The structural attributes of a corpus (s-attributes) can be used to generate subcorpora (i.e., a subcorpus class object) by applying the subset-method. To obtain a subcorpus, the subset-method can be applied on a corpus represented by a corpus object, a length-one character vector (as a shortcut), and on a subcorpus object.

Usage

## S4 method for signature 'corpus'
subset(x, subset, regex = FALSE, ...)

## S4 method for signature 'character'
subset(x, ...)

## S4 method for signature 'subcorpus'
subset(x, subset, ...)

## S4 method for signature 'remote_corpus'
subset(x, subset)

Arguments

x
A corpus or subcorpus object. A corpus may also be specified by a length-one character vector.

subset
A logical expression indicating elements or rows to keep. The expression may be unevaluated (using quote or bquote).

regex
A logical value. If TRUE, values for s-attributes defined using the three dots (...) are interpreted as regular expressions and passed into a grep call for subsetting a table with the regions and values of structural attributes. If FALSE (the default), values for s-attributes must match exactly.

...
An expression that will be used to create a subcorpus from s-attributes.

See Also
The methods applicable for the subcorpus object resulting from subsetting a corpus or subcorpus are described in the documentation of the subcorpus-class. Note that the subset-method can also be applied to textstat-class objects (and objects inheriting from this class).

Examples

use("polmineR")

# examples for standard and non-standard evaluation
a <- corpus("GERMAPARLMINI")

# subsetting a corpus object using non-standard evaluation
sc <- subset(a, speaker == "Angela Dorothea Merkel")
sc <- subset(a, speaker == "Angela Dorothea Merkel" & date == "2009-10-28")
sc <- subset(a, grepl("Merkel", speaker))
sc <- subset(a, grepl("Merkel", speaker) & date == "2009-10-28")

# subsetting corpus specified by character vector
sc <- subset("GERMAPARLMINI", grepl("Merkel", speaker))
sc <- subset("GERMAPARLMINI", speaker == "Angela Dorothea Merkel")
sc <- subset("GERMAPARLMINI", speaker == "Angela Dorothea Merkel" & date == "2009-10-28")
sc <- subset("GERMAPARLMINI", grepl("Merkel", speaker) & date == "2009-10-28")

# subsetting a corpus using the (old) logic of the partition-method
sc <- subset(a, speaker = "Angela Dorothea Merkel")
sc <- subset(a, speaker = "Angela Dorothea Merkel", date = "2009-10-28")
sc <- subset(a, speaker = "Merkel", regex = TRUE)
sc <- subset(a, speaker = c("Merkel", "Kauder"), regex = TRUE)
sc <- subset(a, speaker = "Merkel", date = "2009-10-28", regex = TRUE)

# providing the value for s-attribute as a variable
who <- "Volker Kauder"
sc <- subset(a, quote(speaker == who))

# use bquote for quasiquotation when using a variable for subsetting in a loop
for (who in c("Angela Dorothea Merkel", "Volker Kauder", "Ronald Pofalla")){
  sc <- subset(a, bquote(speaker == .(who)))
  if (interactive()) print(size(sc))
}

# equivalent procedure with lapply (DOES NOT WORK YET)
b <- lapply(
  c("Angela Dorothea Merkel", "Volker Kauder", "Ronald Pofalla"),
  function(who) subset(a, bquote(speaker == .(who)))
)
sapply(b, size)

---

s_attributes

Get s-attributes.

Description

Structural annotations (s-attributes) of a corpus capture metainformation for regions of tokens. The `s_attributes`-method offers high-level access to the s-attributes present in a corpus or subcorpus, or the values of s-attributes in a corpus/partition.

Usage

`s_attributes(.Object, ...)`
## s_attributes

```
## S4 method for signature 'character'
s_attributes(.Object, s_attribute = NULL, unique = TRUE, regex = NULL, ...)

## S4 method for signature 'corpus'
s_attributes(.Object, s_attribute = NULL, unique = TRUE, regex = NULL, ...)

## S4 method for signature 'slice'
s_attributes(.Object, s_attribute = NULL, unique = TRUE, ...)

## S4 method for signature 'partition'
s_attributes(.Object, s_attribute = NULL, unique = TRUE, ...)

## S4 method for signature 'subcorpus'
s_attributes(.Object, s_attribute = NULL, unique = TRUE, ...)

## S4 method for signature 'call'
s_attributes(.Object, corpus)

## S4 method for signature 'remote_corpus'
s_attributes(.Object, ...)

## S4 method for signature 'remote_partition'
s_attributes(.Object, ...)
```

**Arguments**

- `.Object` A corpus, subcorpus, partition object, or a call. A corpus can also be specified by a length-one character vector.
- `...` To maintain backward compatibility, if argument `sAttribute` (deprecated) is used. If `.Object` is a `remote_corpus` or `remote_subcorpus` object, the three dots (`...`) are used to pass arguments. Hence, it is necessary to state the names of all arguments to be passed explicitly.
- `s_attribute` The name of a specific s-attribute.
- `unique` A logical value, whether to return unique values.
- `regex` A regular expression passed into `grep` to filter return value by applying a regex.
- `corpus` A corpus-object or a length one character vector denoting a corpus.

**Details**

Importing XML into the Corpus Workbench (CWB) turns elements and element attributes into so-called "s-attributes". There are two basic uses of the `s_attributes`-method: If the argument `s_attribute` is `NULL` (default), the return value is a character vector with all s-attributes present in a corpus.

If `s_attribute` is the name of a specific s-attribute (a length-one character vector), the values of the s-attributes available in the corpus/partition are returned.
If argument unique is FALSE, the full sequence of the s_attributes is returned, which is a useful building block for decoding a corpus.

If argument s_attributes is a character providing several s-attributes, the method will return a data.table. If unique is TRUE, all unique combinations of the s-attributes will be reported by the data.table.

If Object is a call, the s_attributes-method will return a character vector with the s-attributes occurring in the call. This usage is relevant internally to implement the subset method to generate a subcorpus using non-standard evaluation. Usually it will not be relevant in an interactive session.

**Value**

A character vector (s-attributes, or values of s-attributes).

**Examples**

```r
use("polmineR")

s_attributes("GERMAPARLMINI")
s_attributes("GERMAPARLMINI", "date") # dates of plenary meetings
s_attributes("GERMAPARLMINI", s_attribute = c("date", "party"))
s_attributes(corpus("GERMAPARLMINI"))
p <- partition("GERMAPARLMINI", date = "2009-11-10")
s_attributes(p)
s_attributes(p, "speaker") # get names of speakers

# Get s-attributes occurring in a call
s_attributes(quote(grep("Merkel", speaker)), corpus = "GERMAPARLMINI")
s_attributes(quote(speaker == "Angela Merkel"), corpus = "GERMAPARLMINI")
s_attributes(quote(speaker != "Angela Merkel"), corpus = "GERMAPARLMINI")
s_attributes(
  quote(speaker == "Angela Merkel" & date == "2009-10-28"),
  corpus = "GERMAPARLMINI"
)
```

---

**terms**

*Get terms in partition or corpus.*

**Description**

Get terms in partition or corpus.

**Usage**

```r
## S4 method for signature 'slice'
terms(x, p_attribute, regex = NULL, ...)

## S4 method for signature 'partition'
terms(x, p_attribute, regex = NULL, ...)
```
## S4 method for signature 'subcorpus'
\texttt{terms(x, p\_attribute, regex = NULL, \ldots)}

## S4 method for signature 'character'
\texttt{terms(x, p\_attribute, regex = NULL, robust = FALSE, \ldots)}

### Arguments

- \textit{x}: an atomic character vector with a corpus id or partition object
- \textit{p\_attribute}: the p-attribute to be analyzed
- \textit{regex}: regular expression(s) to filter results
- \textit{\ldots}: for backward compatibility
- \textit{robust}: logical, whether to check for potential failures

### Examples

```r
use("polmineR")

session <- partition("GERMAPARLMINI", date = "2009-10-27")

words <- terms(session, "word")

terms(session, p\_attribute = "word", regex = "^Arbeit.*")

terms(session, p\_attribute = "word", regex = c("Arbeit.*", ".*arbeit"))

```

---

### Description

The \texttt{textstat-class} (technically an S4 class) serves as a superclass for the classes \texttt{features}, \texttt{context}, and \texttt{partition}. Usually, the class will not be used directly. It offers a set of standard generic methods (such as \texttt{head}, \texttt{tail}, \texttt{dim}, \texttt{nrow}, \texttt{colnames}) its childs inherit. The core feature of \texttt{textstat} and its childs is a data\_table in the slot \texttt{stat} for keeping data on text statistics of a corpus, or a partition.

### Usage

```r
## S4 method for signature 'textstat'
name(x)

## S4 method for signature 'character'
name(x)

## S4 replacement method for signature 'textstat'
name(x) <- value
```
## S4 method for signature 'textstat'
round(x, digits = 2L)

## S4 method for signature 'textstat'
sort(x, by, decreasing = TRUE)

as.bundle(object, ...)

## S4 method for signature 'textstat,textstat'
e1 + e2

## S4 method for signature 'textstat'
subset(x, subset)

## S3 method for class 'textstat'
as.data.table(x, ...)

## S4 method for signature 'textstat'
show(object)

## S4 method for signature 'textstat'
p_attributes(.Object)

## S4 method for signature 'textstat'
knit_print(x, options = knitr::opts_chunk, ...)

## S4 method for signature 'textstat'
get_corpus(x)

## S4 method for signature 'textstat'
format(x, digits = 2L)

## S4 method for signature 'textstat'
view(.Object)

### Arguments

- **x**
  - A textstat object.

- **value**
  - A character vector to assign as name to slot name of a textstat class object.

- **digits**
  - Number of digits.

- **by**
  - Column that will serve as the key for sorting.

- **decreasing**
  - Logical, whether to return decreasing order.

- **object**
  - A textstat object

- **...**
  - Argument that will be passed into a call of the format method on the object x.

- **e1**
  - A textstat object.
textstat-class

```
e2          Another textstat object.
subset      A logical expression indicating elements or rows to keep.
.Object     A textstat object.
options     Chunk options.
```

Details

A head-method will return the first rows of the data.table in the stat-slot. Use argument n to specify the number of rows.

A tail-method will return the last rows of the data.table in the stat-slot. Use argument n to specify the number of rows.

The methods dim, nrow and ncol will return information on the dimensions, the number of rows, or the number of columns of the data.table in the stat-slot, respectively.

Objects derived from the textstat class can be indexed with simple square brackets ('[]') to get rows specified by an numeric/integer vector, and with double square brackets ('[[']) to get specific columns from the data.table in the slot stat.

The colnames-method will return the column names of the data-table in the slot stat.

The methods as.data.table, and as.data.frame will extract the data.table in the slot stat as a data.table, or data.frame, respectively.

textstat objects can have a name, which can be retrieved, and set using the name-method and name<-, respectively.

The round()-method looks up all numeric columns in the data.table in the stat-slot of the textstat object and rounds values of these columns to the number of decimal places specified by argument digits.

The knit_print method will be called by knitr to render 'textstat' objects or objects inheriting from the 'textstat' class as a DataTable htmlwidget when rendering a R Markdown document as html. It will usually be necessary to explicitly state "render = knit_print" in the chunk options. The option 'polmineR.pagelength' controls the number of lines displayed in the resulting 'htmlwidget'. Note that including htmlwidgets in html documents requires that pandoc is installed. To avoid an error, a formatted data.table is returned by knit_print if pandoc is not available.

The format()-method returns a pretty-printed and minimized version of the data.table in the stat-slot of the textstat-object. It will round all numeric columns to the number of decimal numbers specified by digits, and drop all columns with token ids. The return value is a data.table.

Slots

```
p_attribute Object of class character, p-attribute of the query.
corpus      A corpus specified by a length-one character vector.
stat        A data.table with statistical information.
name        The name of the object.
annotation_cols A character vector, column names of data.table in slot stat that are annotations.
encoding    A length-one character vector, the encoding of the corpus.
```
Examples

```r
use("polmineR")
P <- partition("GERMAPARLMINI", date = ".*", p_attribute = "word", regex = TRUE)
y <- cooccurrences(P, query = "Arbeit")

# generics defined in the polmineR package
x <- count("REUTERS", p_attribute = "word")
name(x) <- "count_reuters"
name(x)
get_corpus(x)

# Standard generic methods known from data.frames work for objects inheriting
# from the textstat class
head(y)
tail(y)
nrow(y)
ncol(y)
dim(y)
colnames(y)

# Use brackets for indexing

## Not run:
y[1:25]
y[,c("word", "ll")]
y[1:25, "word"]
y[1:25][["word"]]
y[which(y["word"] %in% c("Arbeit", "Sozial"))]
y[ y["word"] %in% c("Arbeit", "Sozial") ]

## End(Not run)
sc <- partition("GERMAPARLMINI", speaker = "Angela Dorothea Merkel")
cnt <- count(sc, p_attribute = c("word", "pos"))
cnt_min <- subset(cnt, pos %in% c("NN", "ADJA"))
cnt_min <- subset(cnt, pos == "NE")

# Get statistics in textstat object as data.table
count_dt <- corpus("REUTERS") %>%
  subset(grep("saudi-arabia", places)) %>%
  count(p_attribute = "word") %>%
  as.data.table()
```

### tooltips

Add tooltips to text output.

**Description**

Highlight tokens based on exact match, a regular expression or corpus position in kwic output or html document.
Usage

tooltips(.Object, tooltips, ...)

## S4 method for signature 'character'
tooltips(.Object, tooltips = list())

## S4 method for signature 'html'
tooltips(.Object, tooltips = list())

## S4 method for signature 'kwic'
tooltips(.Object, tooltips, regex = FALSE, ...)

Arguments

.Object A html or character object with html.
tooltips A named list of character vectors, the names need to match colors in the list provided to param highlight. The value of the character vector is the tooltip to be displayed.
... Further arguments are interpreted as assignments of tooltips to tokens.
regex Logical, whether character vector values of argument tooltips are interpreted as regular expressions.

Examples

use("polmineR")

P <- partition("REUTERS", places = "argentina")
H <- html(P)
Y <- highlight(H, lightgreen = "higher")
T <- tooltips(Y, list(lightgreen = "Further information"))
if (interactive()) T

# Using the tooltips-method in a pipe ...
h <- P %>%
  html() %>%
  highlight(yellow = c("barrels", "oil", "gas")) %>%
tooltips(list(yellow = "energy"))

trim

trim an object

Description

Method to trim and adjust objects by applying thresholds, minimum frequencies etc. It can be applied to context, features, context, partition and partition_bundle objects.
Usage

trim(object, ...)

## S4 method for signature 'TermDocumentMatrix'
trim(
    object,
    termsToKeep = NULL,
    termsToDrop = NULL,
    docsToKeep = NULL,
    docsToDrop = NULL,
    verbose = TRUE
)

## S4 method for signature 'DocumentTermMatrix'
trim(object, ...)

punctuation

Arguments

object the object to be trimmed
...
  further arguments
termsToKeep ...
termsToDrop ...
docsToKeep ...
docsToDrop ...
verbose logical

Format

An object of class character of length 13.

Author(s)

Andreas Blaette

| t_test | Perform t-test. |

Description

Compute t-scores to find collocations.
Usage

t_test(.Object)

## S4 method for signature 'context'
t_test(.Object)

Arguments

,Object A context or features object

Details

The calculation of the t-test is based on the formula

\[ t = \frac{\bar{x} - \mu}{\sqrt{s^2/N}} \]

where \( \mu \) is the mean of the distribution, \( x \) the sample mean, \( s^2 \) the sample variance, and \( N \) the sample size.

Following Manning and Schuetze (1999), to test whether two tokens (a and b) are a collocation, the sample mean \( \mu \) is the number of observed co-occurrences of a and b divided by corpus size \( N \):

\[ \mu = \frac{o_{ab}}{N} \]

For the mean of the distribution \( \bar{x} \), maximum likelihood estimates are used. Given that we know the number of observations of token a, \( o_a \), the number of observations of b, \( o_b \) and the size of the corpus \( N \), the probabilities for the tokens a and b, and for the co-occurrence of a and b are as follows, if independence is assumed:

\[ P(a) = \frac{o_a}{N} \]
\[ P(b) = \frac{o_b}{N} \]
\[ P(ab) = P(a)P(b) \]

See the examples for a sample calculation of the t-test, and Evert (2005: 83) for a critical discussion of the "highly questionable" assumptions when using the t-test for detecting co-occurrences.

References

See Also

Other statistical methods: chisquare(), ll(), pmi()

Examples

use("polmineR")
y <- cooccurrences("REUTERS", query = "oil", left = 1L, right = 0L, method = "t_test")
# The critical value (for a = 0.005) is 2.579, so "crude" is a collocation
# of "oil" according to t-test.

# A sample calculation
count_oil <- count("REUTERS", query = "oil")
count_crude <- count("REUTERS", query = "crude")
count_crude_oil <- count("REUTERS", query = "crude" "oil", cqp = TRUE)

p_crude <- count_crude$count / size("REUTERS")
p_oil <- count_oil$count / size("REUTERS")
p_crude_oil <- p_crude * p_oil

x <- count_crude_oil$count / size("REUTERS")
t_value <- (x - p_crude_oil) / sqrt(x / size("REUTERS"))
# should be identical with previous result:
as.data.frame(subset(y, word == "crude"))$t_test

Description

Use CWB indexed corpora in R data packages by adding registry file to session registry.

Usage

use(pkg, lib.loc = .libPaths(), tmp = FALSE, verbose = TRUE)

Arguments

pkg A package including at least one CWB indexed corpus.
lib.loc A character vector with path names of R libraries.
tmp Whether to use a temporary data directory.
verbose Logical, whether to output status messages.
pkg is expected to be an installed data package that includes CWB indexed corpora. The use-function will add the registry files describing the corpus (or the corpora) to the session registry directory and adjust the path pointing to the data in the package.

The registry files within the package are assumed to be in the subdirectory .extdata/cwb/registry of the installed package. The data directories for corpora are assumed to be in a subdirectory named after the corpus (lower case) in the package subdirectory .extdata/cwb/indexed_corpora/. When adding a corpus to the registry, templates for formatting fulltext output are reloaded.

If the path to the data directory in a package includes a non-ASCII character, binary data files of the corpora in package are copied to a subdirectory of the per-session temporary data directory.

See Also

To get the session registry directory, see registry; to reset the registry, see registry_reset.

Examples

```r
use("polmineR")
corpus()
```

---

view

*Inspect object using View().*

Description

Inspect object using View().

Usage

```r
view(.Object, ...)
```

Arguments

- `.Object` an object
- `...` further parameters
Description

Apply Weight to Matrix

Usage

weigh(.Object, ...)

## S4 method for signature 'TermDocumentMatrix'
weigh(.Object, method = "tfidf")

## S4 method for signature 'DocumentTermMatrix'
weigh(.Object, method = "tfidf")

## S4 method for signature 'count'
weigh(.Object, with)

## S4 method for signature 'count_bundle'
weigh(.Object, with, progress = TRUE)

Arguments

.Object A matrix, or a count-object.
... further parameters
.method The kind of weight to apply.
.with A data.table used to weigh p-attributes. A column 'weight' with term weights is required, and columns with the p-attributes of .Object for matching.
.progress Logical, whether to show a progress bar.

Examples

## Not run:
