Appalachia

Annual maximum streamflow in central Appalachia

## **Description**

Index

The data on annual maximum streamflow at 104 gaging stations in the central Appalachia region of the United States contains the sample L-moments ratios (L-CV, L-skewness and L-kurtosis) as used by Hosking and Wallis (1997) to illustrate regional frequency analysis (RFA).

# Usage

data(Appalachia)

#### **Format**

A data frame with 104 observations on the following 3 variables:

L-CV L-coefficient of variation

L-skewness L-coefficient of skewness

L-kurtosis L-coefficient of kurtosis

## **Details**

The sample L-moment ratios (L-CV, L-skewness and L-kurtosis) of a site are regarded as a point in three dimensional space.

# **Examples**

```
data(Appalachia)
# plot a matrix of scatterplots
pairs(Appalachia,
      main="Appalachia data set",
      bg=c("red", "green3", "blue"))
mcd<-CovMcd(Appalachia)</pre>
mcd
plot(mcd, which="dist", class=TRUE)
plot(mcd, which="dd", class=TRUE)
## identify the discordant sites using robust distances and compare
## to the classical ones
mcd <- CovMcd(Appalachia)</pre>
rd <- sqrt(getDistance(mcd))</pre>
ccov <- CovClassic(Appalachia)</pre>
cd <- sqrt(getDistance(ccov))</pre>
r.out <- which(rd > sqrt(qchisq(0.975,3)))
c.out <- which(cd > sqrt(qchisq(0.975,3)))
cat("Robust: ", length(r.out), " outliers: ", r.out,"\n")
cat("Classical: ", length(c.out), " outliers: ", c.out,"\n")
```

biplot-methods

Biplot for Principal Components (objects of class 'Pca')

## **Description**

Produces a biplot from an object (derived from) Pca-class.

# Usage

```
## S4 method for signature 'Pca'
biplot(x, choices=1L:2L, scale=1, ...)
```

# Arguments

x an object of class (derived from) "Pca".

choices length 2 vector specifying the components to plot. Only the default is a biplot in

the strict sense.

6 bus

scale The variables are scaled by lambda ^ scale and the observations are scaled by

lambda ^ (1-scale) where lambda are the singular values as computed by the Principal Components function. Normally 0 <= scale <= 1, and a warning will

be issued if the specified scale is outside this range.

... optional arguments to be passed to the internal graphical functions.

#### Side Effects

a plot is produced on the current graphics device.

#### Methods

**biplot** signature(x = Pca): Plot a biplot, i.e. represent both the observations and variables of a matrix of multivariate data on the same plot. See also biplot.princomp.

#### References

Gabriel, K. R. (1971). The biplot graphical display of matrices with applications to principal component analysis. *Biometrika*, **58**, 453–467.

#### See Also

Pca-class, PcaClassic, PcaRobust-class.

# **Examples**

```
require(graphics)
biplot(PcaClassic(USArrests, k=2))
```

bus

Automatic vehicle recognition data

## **Description**

The data set bus (Hettich and Bay, 1999) corresponds to a study in automatic vehicle recognition (see Maronna et al. 2006, page 213, Example 6.3)). This data set from the Turing Institute, Glasgow, Scotland, contains measures of shape features extracted from vehicle silhouettes. The images were acquired by a camera looking downward at the model vehicle from a fixed angle of elevation. Each of the 218 rows corresponds to a view of a bus silhouette, and contains 18 attributes of the image.

#### Usage

```
data(bus)
```

bus 7

## **Format**

A data frame with 218 observations on the following 18 variables:

- V1 compactness
- V2 circularity
- V3 distance circularity
- V4 radius ratio
- V5 principal axis aspect ratio
- V6 maximum length aspect ratio
- V7 scatter ratio
- V8 elongatedness
- V9 principal axis rectangularity
- V10 maximum length rectangularity
- V11 scaled variance along major axis
- V12 scaled variance along minor axis
- V13 scaled radius of gyration
- V14 skewness about major axis
- V15 skewness about minor axis
- V16 kurtosis about minor axis
- V17 kurtosis about major axis
- V18 hollows ratio

bushmiss

Campbell Bushfire Data with added missing data items

#### Description

This data set is based on the bushfire data set which was used by Campbell (1984) to locate bushfire scars - see bushfire in package robustbase. The original dataset contains satelite measurements on five frequency bands, corresponding to each of 38 pixels.

# Usage

```
data(bushmiss)
```

#### **Format**

A data frame with 190 observations on 6 variables.

The original data set consists of 38 observations in 5 variables. Based on it four new data sets are created in which some of the data items are replaced by missing values with a simple "missing completely at random "mechanism. For this purpose independent Bernoulli trials are realized for each data item with a probability of success 0.1, 0.2, 0.3, 0.4, where success means that the corresponding item is set to missing. The obtained five data sets, including the original one (each with probability of a data item to be missing equal to 0, 0.1, 0.2, 0.3 and 0.4 which is reflected in the new variable MPROB) are merged. (See also Beguin and Hulliger (2004).)

10 Cars

## **Examples**

```
## The following code will result in exactly the same output
## as the one obtained from the original data set
data(bushmiss)
bf <- bushmiss[bushmiss$MPROB==0,1:5]</pre>
plot(bf)
covMcd(bf)
## Not run:
## This is the code with which the missing data were created:
##
## Creates a data set with missing values (for testing purposes)
## from a complete data set 'x'. The probability of
## each item being missing is 'pr' (Bernoulli trials).
##
getmiss <- function(x, pr=0.1)</pre>
{
    n \leftarrow nrow(x)
    p \leftarrow ncol(x)
    done <- FALSE
    iter <- 0
    while(iter <= 50){</pre>
        bt <- rbinom(n*p, 1, pr)</pre>
        btmat <- matrix(bt, nrow=n)</pre>
        btmiss <- ifelse(btmat==1, NA, 0)</pre>
        y <- x+btmiss
        if(length(which(rowSums(nanmap(y)) == p)) == 0)
             return (y)
        iter <- iter + 1
    }
    У
}
## End(Not run)
```

Cars

Consumer reports car data: dimensions

# **Description**

A data frame containing 11 variables with different dimensions of 111 cars

## Usage

```
data(Cars)
```

Cars 11

## **Format**

A data frame with 111 observations on the following 11 variables.

```
length a numeric vector
wheelbase a numeric vector
width a numeric vector
height a numeric vector
front.hd a numeric vector
rear.hd a numeric vector
front.leg a numeric vector
rear.seating a numeric vector
front.shoulder a numeric vector
luggage a numeric vector
```

# **Examples**

```
data(Cars)

## Plot a pairwise scaterplot matrix
    pairs(Cars[,1:6])

    mcd <- CovMcd(Cars[,1:6])
    plot(mcd, which="pairs")

## Start with robust PCA
    pca <- PcaHubert(Cars, k=ncol(Cars), kmax=ncol(Cars))
    pca

## Compare with the classical PCA
    prcomp(Cars)

## or
    PcaClassic(Cars, k=ncol(Cars), kmax=ncol(Cars))</pre>
```

12 Cascades

```
## If you want to print the scores too, use
    print(pca, print.x=TRUE)
## Using the formula interface
   PcaHubert(~., data=Cars, k=ncol(Cars), kmax=ncol(Cars))
## To plot the results:
   plot(pca)
                                  # distance plot
   pca2 <- PcaHubert(Cars, k=4)</pre>
                                  # PCA diagnostic plot (or outlier map)
   plot(pca2)
## Use the standard plots available for prcomp and princomp
    screeplot(pca)
                      # it is interesting with all variables
    biplot(pca)
                      # for biplot we need more than one PCs
## Restore the covraiance matrix
    py <- PcaHubert(Cars, k=ncol(Cars), kmax=ncol(Cars))</pre>
    cov.1 <- py@loadings %*% diag(py@eigenvalues) %*% t(py@loadings)</pre>
    cov.1
```

Cascades

Annual precipitation totals for the North Cascades region

# **Description**

The data on annual precipitation totals for the North Cascades region contains the sample L-moments ratios (L-CV, L-skewness and L-kurtosis) for 19 sites as used by Hosking and Wallis (1997), page 53, Table 3.4, to illustrate screening tools for regional frequency analysis (RFA).

#### Usage

```
data(Cascades)
```

#### **Format**

A data frame with 19 observations on the following 3 variables.

L-CV L-coefficient of variation

L-skewness L-coefficient of skewness

L-kurtosis L-coefficient of kurtosis

# **Details**

The sample L-moment ratios (L-CV, L-skewness and L-kurtosis) of a site are regarded as a point in three dimensional space.

cat("Classical: ", length(c.out), " outliers: ", c.out,"\n")
```

Cov-class

Class "Cov" – a base class for estimates of multivariate location and scatter

# Description

The class Cov represents an estimate of the multivariate location and scatter of a data set. The objects of class Cov contain the classical estimates and serve as base for deriving other estimates, i.e. different types of robust estimates.

#### **Objects from the Class**

Objects can be created by calls of the form new("Cov", ...), but the usual way of creating Cov objects is a call to the function Cov which serves as a constructor.

14 Cov-class

#### **Slots**

```
call: Object of class "language"

cov: covariance matrix

center: location

n.obs: number of observations used for the computation of the estimates

mah: mahalanobis distances

det: determinant

flag: flags (FALSE if suspected an outlier)

method: a character string describing the method used to compute the estimate: "Classic"

singularity: a list with singularity information for the covariance matrix (or NULL of not singular)

X: data
```

#### Methods

```
getCenter signature(obj = "Cov"): location vector
getCov signature(obj = "Cov"): covariance matrix
getCorr signature(obj = "Cov"): correlation matrix
getData signature(obj = "Cov"): data frame
getDistance signature(obj = "Cov"): distances
getEvals signature(obj = "Cov"): Computes and returns the eigenvalues of the covariance ma-
getDet signature(obj = "Cov"): Computes and returns the determinant of the covariance matrix
     (or 0 if the covariance matrix is singular)
getShape signature(obj = "Cov"): Computes and returns the shape matrix corresponding to the
    covariance matrix (i.e. the covariance matrix scaled to have determinant =1)
getFlag signature(obj = "Cov"): Flags observations as outliers if the corresponding mahalanobis
     distance is larger then qchisq(prob, p) where prob defaults to 0.975.
isClassic signature(obj = "Cov"): returns TRUE by default. If necessary, the robust classes will
    override
plot signature(x = "Cov"): plot the object
show signature(object = "Cov"): display the object
summary signature(object = "Cov"): calculate summary information
```

```
showClass("Cov")
```

CovClassic 15

| CovClassic | Classical Estimates of Multivariate Location and Scatter |  |
|------------|--|--|
|            |  |  |

# Description

Computes the classical estimates of multivariate location and scatter. Returns an S4 class CovClassic with the estimated center, cov, Mahalanobis distances and weights based on these distances.

## Usage

```
CovClassic(x, unbiased=TRUE)
Cov(x, unbiased=TRUE)
```

# Arguments

x a matrix or data frame. As usual, rows are observations and columns are vari-

ables.

unbiased whether to return the unbiased estimate of the covariance matrix. Default is

unbiased = TRUE

#### Value

An object of class "CovClassic".

CovControl-class

Class "CovControl" is a VIRTUAL base control class

# **Description**

The class "CovControl" is a VIRTUAL base control class for the derived classes representing the control parameters for the different robust methods

## **Arguments**

trace whether to print intermediate results. Default is trace = FALSE

tolSolve numeric tolerance to be used for inversion (solve) of the covariance matrix in

mahalanobis.

# **Objects from the Class**

A virtual Class: No objects may be created from it.

## Methods

No methods defined with class "CovControl" in the signature.

## Author(s)

Valentin Todorov <valentin.todorov@chello.at>

## References

Todorov V & Filzmoser P (2009), An Object Oriented Framework for Robust Multivariate Analysis. *Journal of Statistical Software*, **32**(3), 1–47. doi:10.18637/jss.v032.i03.

18 CovControlMcd

| CovControlMcd | Constructor function for objects of class "CovControlMcd" |
|---------------|---|
| COVCONCIONICA | Constructor function for objects of class CovControllact  |

#### **Description**

This function will create a control object CovControlMcd containing the control parameters for CovMcd

#### Usage

```
CovControlMcd(alpha = 0.5, nsamp = 500, scalefn=NULL, maxcsteps=200,
seed = NULL, trace= FALSE, use.correction = TRUE)
```

## **Arguments**

alpha numeric parameter controlling the size of the subsets over which the determi-

nant is minimized, i.e., alpha\*n observations are used for computing the deter-

minant. Allowed values are between 0.5 and 1 and the default is 0.5.

nsamp number of subsets used for initial estimates or "best", "exact" or "deterministic".

Default is nsamp = 500. For nsamp="best" exhaustive enumeration is done, as long as the number of trials does not exceed 5000. For "exact", exhaustive enumeration will be attempted however many samples are needed. In this case a warning message will be displayed saying that the computation can take a very

long time

For "deterministic", the *deterministic* MCD is computed; as proposed by Hubert et al. (2012) it starts from the h most central observations of six (deter-

ministic) estimators.

scalefn function to compute a robust scale estimate or character string specifying a

rule determining such a function, see rrcov.control.

maxcsteps maximal number of concentration steps in the deterministic MCD; should not

be reached.

seed starting value for random generator. Default is seed = NULL trace whether to print intermediate results. Default is trace = FALSE

use.correction whether to use finite sample correction factors. Default is use.correction=TRUE

#### Value

A CovControlMcd object

# Author(s)

Valentin Todorov <valentin.todorov@chello.at>

#### References

Todorov V & Filzmoser P (2009), An Object Oriented Framework for Robust Multivariate Analysis. *Journal of Statistical Software*, **32**(3), 1–47. doi:10.18637/jss.v032.i03.

CovControlMcd-class 19

## **Examples**

```
## the following two statements are equivalent
ctrl1 <- new("CovControlMcd", alpha=0.75)
ctrl2 <- CovControlMcd(alpha=0.75)

data(hbk)
CovMcd(hbk, control=ctrl1)</pre>
```

CovControlMcd-class

Class 'CovControlMcd' - contains control parameters for CovMcd

## **Description**

This class extends the CovControl class and contains the control parameters for "CovMcd"

## **Objects from the Class**

Objects can be created by calls of the form new("CovControlMcd", ...) or by calling the constructor-function CovControlMcd.

#### Slots

alpha: numeric parameter controlling the size of the subsets over which the determinant is minimized, i.e., alpha\*n observations are used for computing the determinant. Allowed values are between 0.5 and 1 and the default is 0.5.

nsamp number of subsets used for initial estimates or "best", "exact" or "deterministic". Default is nsamp = 500. For nsamp="best" exhaustive enumeration is done, as long as the number of trials does not exceed 5000. For "exact", exhaustive enumeration will be attempted however many samples are needed. In this case a warning message will be displayed saying that the computation can take a very long time.

For "deterministic", the *deterministic* MCD is computed; as proposed by Hubert et al. (2012) it starts from the h most central observations of six (deterministic) estimators.

**scalefn** function to compute a robust scale estimate or character string specifying a rule determining such a function.

maxcsteps maximal number of concentration steps in the deterministic MCD; should not be reached.

seed: starting value for random generator. Default is seed = NULL

use.correction: whether to use finite sample correction factors. Default is use.correction=TRUE. trace, tolSolve: from the "CovControl" class.

#### **Extends**

```
Class "CovControl", directly.
```

20 CovControlMest

## Methods

**restimate** signature(obj = "CovControlMcd"): the generic function restimate allows the different methods for robust estimation to be used polymorphically - this function will call CovMcd passing it the control object and will return the obtained CovRobust object

## Author(s)

Valentin Todorov <valentin.todorov@chello.at>

```

CovControlMrcd 25

|  | CovControlMrcd | Constructor function for objects of class "CovControlMrcd" |
|--|----------------|--|
|--|----------------|--|

# Description

This function will create a control object CovControlMrcd containing the control parameters for CovMrcd

# Usage

```
CovControlMrcd(alpha = 0.5, h=NULL, maxcsteps=200, rho=NULL,
    target=c("identity", "equicorrelation"), maxcond=50,
    trace= FALSE)
```

# Arguments

| alpha     | numeric parameter controlling the size of the subsets over which the determinant is minimized, i.e., alpha*n observations are used for computing the determinant. Allowed values are between 0.5 and 1 and the default is 0.5.  |
|-----------|---|
| h         | the size of the subset (can be between ceiling(n/2) and n). Normally NULL and then it h will be calculated as h=ceiling(alpha*n). If h is provided, alpha will be calculated as alpha=h/n.  |
| maxcsteps | maximal number of concentration steps in the deterministic MCD; should not be reached.  |
| rho       | regularization parameter. Normally NULL and will be estimated from the data.  |
| target    | structure of the robust positive definite target matrix: a) "identity": target matrix is diagonal matrix with robustly estimated univariate scales on the diagonal or b) "equicorrelation": non-diagonal target matrix that incorporates an equicorrelation structure (see (17) in paper). Default is target="identity" |
| maxcond   | maximum condition number allowed (see step $3.4$ in algorithm 1). Default is maxcond=50   |
| trace     | whether to print intermediate results. Default is trace = FALSE   |

# Value

A CovControlMrcd object

# Author(s)

Valentin Todorov <valentin.todorov@chello.at>

#### References

Todorov V & Filzmoser P (2009), An Object Oriented Framework for Robust Multivariate Analysis. *Journal of Statistical Software*, **32**(3), 1–47. doi:10.18637/jss.v032.i03.

26 CovControlMrcd-class

## **Examples**

```
## the following two statements are equivalent
ctrl1 <- new("CovControlMrcd", alpha=0.75)
ctrl2 <- CovControlMrcd(alpha=0.75)

data(hbk)
CovMrcd(hbk, control=ctrl1)</pre>
```

CovControlMrcd-class Class 'CovControlMrcd' - contains control parameters for CovMrcd()

Description

This class extends the CovControl class and contains the control parameters for "CovMrcd"

## **Objects from the Class**

Objects can be created by calls of the form new("CovControlMrcd", ...) or by calling the constructor-function CovControlMrcd.

#### Slots

alpha: numeric parameter controlling the size of the subsets over which the determinant is minimized, i.e., alpha\*n observations are used for computing the determinant. Allowed values are between 0.5 and 1 and the default is 0.5.

h the size of the subset (can be between ceiling(n/2) and n). Normally NULL and then it h will be calculated as h=ceiling(alpha\*n). If h is provided, alpha will be calculated as alpha=h/n.

maxcsteps maximal number of concentration steps in the deterministic MCD; should not be reached.

**rho** regularization parameter. Normally NULL and will be estimated from the data.

**target** structure of the robust positive definite target matrix: a) "identity": target matrix is diagonal matrix with robustly estimated univariate scales on the diagonal or b) "equicorrelation": non-diagonal target matrix that incorporates an equicorrelation structure (see (17) in paper).

**maxcond** maximum condition number allowed (see step 3.4 in algorithm 1).

```
trace, tolSolve: from the "CovControl" class.
```

#### Extends

```
Class "CovControl", directly.
```

## Methods

restimate signature(obj = "CovControlMrcd"): the generic function restimate allows the different methods for robust estimation to be used polymorphically - this function will call CovMrcd passing it the control object and will return the obtained CovRobust object

CovControlMve 27

data(hbk)
CovMrcd(hbk, control=ctrl1)</pre>
```

CovControlMve

Constructor function for objects of class "CovControlMve"

## **Description**

This function will create a control object CovControlMve containing the control parameters for CovMve

## Usage

```
CovControlMve(alpha = 0.5, nsamp = 500, seed = NULL, trace= FALSE)
```

# **Arguments**

trace

| alpha | numeric parameter controlling the size of the subsets over which the determinant is minimized, i.e., alpha*n observations are used for computing the determinant. Allowed values are between 0.5 and 1 and the default is 0.5.   |
|-------|--|
| nsamp | number of subsets used for initial estimates or "best" or "exact". Default is nsamp = 500. For nsamp="best" exhaustive enumeration is done, as long as the number of trials does not exceed 5000. For "exact", exhaustive enumeration will be attempted however many samples are needed. In this case a warning message will be displayed saying that the computation can take a very long time. |
| seed  | starting value for random generator. Default is seed = NULL  |
|       |  |

whether to print intermediate results. Default is trace = FALSE

28 CovControlMve-class

#### Value

A CovControlMve object

# **Examples**

```
## the following two statements are equivalent
ctrl1 <- new("CovControlMve", alpha=0.75)
ctrl2 <- CovControlMve(alpha=0.75)

data(hbk)
CovMve(hbk, control=ctrl1)</pre>
```

CovControlMve-class

Class 'CovControlMve' - contains control parameters for CovMve

# Description

This class extends the CovControl class and contains the control parameters for "CovMve"

## **Objects from the Class**

Objects can be created by calls of the form new("CovControlMve", ...) or by calling the constructor-function CovControlMve.

#### Slots

alpha: numeric parameter controlling the size of the subsets over which the determinant is minimized, i.e., alpha\*n observations are used for computing the determinant. Allowed values are between 0.5 and 1 and the default is 0.5.

nsamp: number of subsets used for initial estimates or "best" or "exact". Default is nsamp = 500. For nsamp="best" exhaustive enumeration is done, as long as the number of trials does not exceed 5000. For "exact", exhaustive enumeration will be attempted however many samples are needed. In this case a warning message will be displayed saying that the computation can take a very long time.

```
seed: starting value for random generator. Default is seed = NULL trace, tolSolve: from the "CovControl" class.
```

CovControlOgk 29

## **Extends**

```
Class "CovControl", directly.
```

#### Methods

**restimate** signature(obj = "CovControlMve"): the generic function restimate allowes the different methods for robust estimation to be used polymorphically - this function will call CovMve passing it the control object and will return the obtained CovRobust object

## Author(s)

Valentin Todorov <valentin.todorov@chello.at>

#### References

Todorov V & Filzmoser P (2009), An Object Oriented Framework for Robust Multivariate Analysis. *Journal of Statistical Software*, **32**(3), 1–47. doi:10.18637/jss.v032.i03.

## **Examples**

```
## the following two statements are equivalent
ctrl1 <- new("CovControlMve", alpha=0.75)
ctrl2 <- CovControlMve(alpha=0.75)

data(hbk)
CovMve(hbk, control=ctrl1)</pre>
```

CovControlOgk

Constructor function for objects of class "CovControlOgk"

## Description

This function will create a control object CovControlOgk containing the control parameters for CovOgk

# Usage

```
CovControlOgk(niter = 2, beta = 0.9, mrob = NULL,
vrob = .vrobGK, smrob = "scaleTau2", svrob = "gk")
```

## **Arguments**

| niter | number of iterations, usually 1 or 2 since iterations beyond the second do not |
|-------|--|
|       | lead to improvement.   |

beta coverage parameter for the final reweighted estimate

mrob function for computing the robust univariate location and dispersion - one could

use the tau scale defined in Yohai and Zamar (1998), see scaleTau2. The  $\ensuremath{\text{C}}$ 

version of this function defined by smrob is the default.

30 CovControlOgk

| vrob  | function for computing robust estimate of covariance between two random vectors - one could use the function proposed by Gnanadesikan and Kettenring (1972), see covOGK(). The C version of this function defined by svrob is the default. |
|-------|--|
| smrob | a string indicating the name of the function for computing the robust univariate location and dispersion - defaults to scaleTau2 - the scale tau function defined in Yohai and Zamar (1998)  |
| svrob | a string indicating the name of the function for computing robust estimate of covariance between two random vectors - defaults gk, the one proposed by Gnanadesikan and Kettenring (1972)  |

## **Details**

If the user does not specify a scale and covariance function to be used in the computations or specifies one by using the arguments smrob and svrob (i.e. the names of the functions as strings), a native code written in C will be called which is by far faster than the R version.

If the arguments mrob and vrob are not NULL, the specified functions will be used via the pure R implementation of the algorithm. This could be quite slow.

#### Value

A CovControlOgk object

32 CovControlSde

# **Examples**

```
## the following two statements are equivalent
ctrl1 <- new("CovControlOgk", beta=0.95)
ctrl2 <- CovControlOgk(beta=0.95)

data(hbk)
CovOgk(hbk, control=ctrl1)</pre>
```

CovControlSde

Constructor function for objects of class "CovControlSde"

# Description

This function will create a control object CovControlSde containing the control parameters for CovSde

# Usage

```
CovControlSde(nsamp = 0, maxres = 0, tune = 0.95, eps = 0.5, prob = 0.99,
    seed = NULL, trace = FALSE, tolSolve = 1e-14)
```

# **Arguments**

| nsamp    | a positive integer giving the number of resamples required; nsamp may not be reached if too many of the p-subsamples, chosen out of the observed vectors, are in a hyperplane. If nsamp = 0 all possible subsamples are taken. If nsamp is omitted, it is calculated to provide a breakdown point of eps with probability prob. |
|----------|---|
| maxres   | a positive integer specifying the maximum number of resamples to be performed including those that are discarded due to linearly dependent subsamples. If maxres is omitted it will be set to 2 times nsamp.  |
| tune     | a numeric value between 0 and 1 giving the fraction of the data to receive non-zero weight. Defaults to $0.95$ .  |
| prob     | a numeric value between 0 and 1 specifying the probability of high breakdown point; used to compute nsamp when nsamp is omitted. Defaults to $0.99$ .   |
| eps      | a numeric value between 0 and 0.5 specifying the breakdown point; used to compute nsamp when nresamp is omitted. Defaults to $0.5$ .  |
| seed     | starting value for random generator. Default is seed = NULL.  |
| trace    | whether to print intermediate results. Default is trace = FALSE.  |
| tolSolve | numeric tolerance to be used for inversion (solve) of the covariance matrix in mahalanobis.   |

# Value

CovMcd

Robust Location and Scatter Estimation via MCD

## **Description**

Computes a robust multivariate location and scatter estimate with a high breakdown point, using the 'Fast MCD' (Minimum Covariance Determinant) estimator.

CovMcd 37

## Usage

### **Arguments**

x a matrix or data frame.

raw.only should only the "raw" estimate be returned.

alpha numeric parameter controlling the size of the subsets over which the determi-

nant is minimized, i.e., alpha\*n observations are used for computing the deter-

minant. Allowed values are between 0.5 and 1 and the default is 0.5.

nsamp number of subsets used for initial estimates or "best", "exact" or "deterministic".

Default is nsamp = 500. For nsamp="best" exhaustive enumeration is done, as long as the number of trials does not exceed 5000. For "exact", exhaustive enumeration will be attempted however many samples are needed. In this case a warning message will be displayed saying that the computation can take a very

long time.

For "deterministic", the *deterministic* MCD is computed; as proposed by Hubert et al. (2012) it starts from the h most central observations of six (deter-

ministic) estimators.

scalefn function to compute a robust scale estimate or character string specifying a

rule determining such a function, see rrcov.control.

maxcsteps maximal number of concentration steps in the deterministic MCD; should not

be reached.

initHsets NULL or a Kxh integer matrix of initial subsets of observations of size h (spec-

ified by the indices in 1:n).

save.hsets (for deterministic MCD) logical indicating if the initial subsets should be re-

turned as initHsets.

seed starting value for random generator. Default is seed = NULL

trace whether to print intermediate results. Default is trace = FALSE

use.correction whether to use finite sample correction factors. Default is use.correction=TRUE

control a control object (S4) of class CovControlMcd-class containing estimation op-

tions - same as these provided in the function specification. If the control object is supplied, the parameters from it will be used. If parameters are passed also in the invocation statement, they will override the corresponding elements of the

control object.

... potential further arguments passed to **robustbase**'s covMcd.

38 CovMcd

### **Details**

This function computes the minimum covariance determinant estimator of location and scatter and returns an S4 object of class CovMcd-class containing the estimates. The implementation of the function is similar to the existing R function covMcd() which returns an S3 object. The MCD method looks for the h(>n/2) observations (out of n) whose classical covariance matrix has the lowest possible determinant. The raw MCD estimate of location is then the average of these h points, whereas the raw MCD estimate of scatter is their covariance matrix, multiplied by a consistency factor and a finite sample correction factor (to make it consistent at the normal model and unbiased at small samples). Both rescaling factors are returned also in the vector raw.cnp2 of length 2. Based on these raw MCD estimates, a reweighting step is performed which increases the finite-sample efficiency considerably - see Pison et al. (2002). The rescaling factors for the reweighted estimates are returned in the vector cnp2 of length 2. Details for the computation of the finite sample correction factors can be found in Pison et al. (2002). The finite sample corrections can be suppressed by setting use.correction=FALSE. The implementation in rrcov uses the Fast MCD algorithm of Rousseeuw and Van Driessen (1999) to approximate the minimum covariance determinant estimator.

## Value

An S4 object of class CovMcd-class which is a subclass of the virtual class CovRobust-class.

CovMcd-class 39

CovMcd-class

MCD Estimates of Multivariate Location and Scatter

# **Description**

This class, derived from the virtual class "CovRobust" accommodates MCD Estimates of multivariate location and scatter computed by the 'Fast MCD' algorithm.

# **Objects from the Class**

Objects can be created by calls of the form new("CovMcd", ...), but the usual way of creating CovMcd objects is a call to the function CovMcd which serves as a constructor.

#### Slots

alpha: Object of class "numeric" - the size of the subsets over which the determinant is minimized (the default is (n+p+1)/2)

quan: Object of class "numeric" - the number of observations on which the MCD is based. If quan equals n.obs, the MCD is the classical covariance matrix.

best: Object of class "Uvector" - the best subset found and used for computing the raw estimates. The size of best is equal to quan

raw.cov: Object of class "matrix" the raw (not reweighted) estimate of location

raw.center: Object of class "vector" - the raw (not reweighted) estimate of scatter

raw.mah: Object of class "Uvector" - mahalanobis distances of the observations based on the raw estimate of the location and scatter

raw.wt: Object of class "Uvector" - weights of the observations based on the raw estimate of the location and scatter

raw.cnp2: Object of class "numeric" - a vector of length two containing the consistency correction factor and the finite sample correction factor of the raw estimate of the covariance matrix

cnp2: Object of class "numeric" - a vector of length two containing the consistency correction factor and the finite sample correction factor of the final estimate of the covariance matrix.

iter, crit, wt: from the "CovRobust" class.

call, cov, center, n.obs, mah, method, singularity, X: from the "Cov" class.

CovMest

Constrained M-Estimates of Location and Scatter

# **Description**

Computes constrained M-Estimates of multivariate location and scatter based on the translated biweight function ('t-biweight') using a High breakdown point initial estimate as defined by Rocke (1996). The default initial estimate is the Minimum Volume Ellipsoid computed with CovMve. The raw (not reweighted) estimates are taken and the covariance matrix is standardized to determinant 1.

# Usage

```
CovMest(x, r = 0.45, arp = 0.05, eps=1e-3, maxiter=120, control, t0, S0, initcontrol)
```

# **Arguments**

| X       | a matrix or data frame.   |
|---------|---|
| r       | required breakdown point. Allowed values are between $(n - p)/(2 * n)$ and 1 and the default is $0.45$              |
| arp     | asympthotic rejection point, i.e. the fraction of points receiving zero weight (see Rocke (1996)). Default is 0.05. |
| eps     | a numeric value specifying the relative precision of the solution of the M-estimate. Defaults to $1e-3$             |
| maxiter | maximum number of iterations allowed in the computation of the M-estimate. Defaults to 120                          |

CovMest 41

| control     | a control object (S4) of class CovControlMest-class containing estimation options - same as these provided in the fucntion specification. If the control object is supplied, the parameters from it will be used. If parameters are passed also in the invocation statement, they will override the corresponding elements of the control object. |
|-------------|---|
| t0          | optional initial high breakdown point estimates of the location. If not supplied MVE will be used.  |
| S0          | optional initial high breakdown point estimates of the scatter. If not supplied MVE will be used.   |
| initcontrol | optional control object - of class CovControl - specifing the initial high break-<br>down point estimates of location and scatter. If not supplied MVE will be used.  |

## **Details**

Rocke (1996) has shown that the S-estimates of multivariate location and scatter in high dimensions can be sensitive to outliers even if the breakdown point is set to be near 0.5. To mitigate this problem he proposed to utilize the translated biweight (or t-biweight) method with a standardization step consisting of equating the median of rho(d) with the median under normality. This is then not an S-estimate, but is instead a constrained M-estimate. In order to make the smooth estimators to work, a reasonable starting point is necessary, which will lead reliably to a good solution of the estimator. In CovMest the MVE computed by CovMve is used, but the user has the possibility to give her own initial estimates.

### Value

An object of class CovMest-class which is a subclass of the virtual class CovRobust-class.

# Note

The psi, rho and weight functions for the M estimation are encapsulated in a virtual S4 class PsiFun from which a PsiBwt class, implementing the translated biweight (t-biweight), is dervied. The base class PsiFun contains also the M-iteration itself. Although not documented and not accessibale directly by the user these classes will form the bases for adding other functions (biweight, LWS, etc.) as well as S-estimates.

## **Examples**

covMest

Constrained M-Estimates of Location and Scatter

# Description

Computes constrained M-Estimates of multivariate location and scatter based on the translated biweight function ('t-biweight') using a High breakdown point initial estimate. The default initial estimate is the Minimum Volume Ellipsoid computed with CovMve. The raw (not reweighted) estimates are taken and the covariance matrix is standardized to determinant 1.

## Usage

```
covMest(x, cor=FALSE, r = 0.45, arp = 0.05, eps=1e-3,
    maxiter=120, control, t0, S0)
```

covMest 43

## **Arguments**

| X       | a matrix or data frame.  |
|---------|--|
| cor     | should the returned result include a correlation matrix? Default is cor = FALSE  |
|         |  |
| r       | required breakdown point. Allowed values are between (n - p)/(2 $\star$ n) and 1 and the default is 0.45   |
| arp     | asympthotic rejection point, i.e. the fraction of points receiving zero weight (see Rocke (1996)). Default is 0.05.  |
| eps     | a numeric value specifying the relative precision of the solution of the M-estimate. Defaults to 1e-3  |
| maxiter | maximum number of iterations allowed in the computation of the M-estimate. Defaults to $120$   |
| control | a list with estimation options - same as these provided in the fucntion specification. If the control object is supplied, the parameters from it will be used. If parameters are passed also in the invocation statement, they will override the corresponding elements of the control object. |
| t0      | optional initial high breakdown point estimates of the location. If not supplied MVE will be used.   |
| SØ      | optional initial high breakdown point estimates of the scatter. If not supplied MVE will be used.  |

### **Details**

Rocke (1996) has shown that the S-estimates of multivariate location and scatter in high dimensions can be sensitive to outliers even if the breakdown point is set to be near 0.5. To mitigate this problem he proposed to utilize the translated biweight (or t-biweight) method with a standardization step consisting of equating the median of rho(d) with the median under normality. This is then not an S-estimate, but is instead a constrained M-estimate. In order to make the smooth estimators to work, a reasonable starting point is necessary, which will lead reliably to a good solution of the estimator. In covMest the MVE computed by CovMve is used, but the user has the possibility to give her own initial estimates.

## Value

An object of class "mest" which is basically a list with the following components. This class is "derived" from "mcd" so that the same generic functions - print, plot, summary - can be used. NOTE: this is going to change - in one of the next revisions covMest will return an S4 class "mest" which is derived (i.e. contains) form class "cov".

| center | the final estimate of location.   |
|--------|---|
| cov    | the final estimate of scatter.  |
| cor    | the estimate of the correlation matrix (only if cor = TRUE).                                |
| mah    | mahalanobis distances of the observations using the M-estimate of the location and scatter. |

44 CovMest-class

X the input data as a matrix. n.obs total number of observations.

method character string naming the method (M-Estimates).

call the call used (see match.call).

### Note

The psi, rho and weight functions for the M estimation are encapsulated in a virtual S4 class PsiFun from which a PsiBwt class, implementing the translated biweight (t-biweight), is dervied. The base class PsiFun contains also the M-iteration itself. Although not documented and not accessibale directly by the user these classes will form the bases for adding other functions (biweight, LWS, etc.) as well as S-estimates.

MM Estimates of Multivariate Location and Scatter

# **Description**

Computes MM-Estimates of multivariate location and scatter starting from an initial S-estimate

### **Usage**

46 CovMMest

## **Arguments**

| x         | a matrix or data frame.  |
|-----------|--|
| bdp       | a numeric value specifying the required breakdown point. Allowed values are between $0.5$ and $1$ and the default is bdp=0.5.  |
| eff       | a numeric value specifying the required efficiency for the MM estimates. Default is $eff=0.95$ .   |
| eff.shape | logical; if TRUE, eff is with regard to shape-efficiency, otherwise location-efficiency. Default is eff. shape=FALSE.  |
| maxiter   | maximum number of iterations allowed in the computation of the S-estimate (bisquare and Rocke type). Default is maxiter=50.  |
| trace     | whether to print intermediate results. Default is trace = FALSE.   |
| tolSolve  | numeric tolerance to be used as a convergence tolerance for the MM-iteration   |
| control   | a control object (S4) of class CovControlMMest-class containing estimation options - same as these provided in the fucntion specification. If the control object is supplied, the parameters from it will be used. If parameters are passed also in the invocation statement, they will override the corresponding elements of the control object. |

## **Details**

CovMrcd

Robust Location and Scatter Estimation via Minimum Regularized Covariance Determonant (MRCD)

## **Description**

Computes a robust multivariate location and scatter estimate with a high breakdown point, using the Minimum Regularized Covariance Determonant (MRCD) estimator.

# Usage

```
CovMrcd(x,
    alpha=control@alpha,
    h=control@h,
    maxcsteps=control@maxcsteps,
    initHsets=NULL, save.hsets=FALSE,
    rho=control@rho,
    target=control@target,
    maxcond=control@maxcond,
    trace=control@trace,
    control=CovControlMrcd())
```

CovMrcd 49

## **Arguments**

| x          | a matrix or data frame.   |
|------------|---|
| alpha      | numeric parameter controlling the size of the subsets over which the determinant is minimized, i.e., alpha*n observations are used for computing the determinant. Allowed values are between 0.5 and 1 and the default is 0.5.  |
| h          | the size of the subset (can be between ceiling(n/2) and n). Normally NULL and then it h will be calculated as h=ceiling(alpha $*$ n). If h is provided, alpha will be calculated as alpha=h/n.  |
| maxcsteps  | maximal number of concentration steps in the deterministic MCD; should not be reached.  |
| initHsets  | NULL or a $Kxh$ integer matrix of initial subsets of observations of size $h$ (specified by the indices in 1:n).  |
| save.hsets | (for deterministic MCD) logical indicating if the initial subsets should be returned as initHsets.  |
| rho        | regularization parameter. Normally NULL and will be estimated from the data.  |
| target     | structure of the robust positive definite target matrix: a) "identity": target matrix is diagonal matrix with robustly estimated univariate scales on the diagonal or b) "equicorrelation": non-diagonal target matrix that incorporates an equicorrelation structure (see (17) in paper). Default is target="identity"                           |
| maxcond    | maximum condition number allowed (see step $3.4$ in algorithm 1). Default is $\max cond=50$   |
| trace      | whether to print intermediate results. Default is trace = FALSE   |
| control    | a control object (S4) of class CovControlMrcd-class containing estimation options - same as these provided in the function specification. If the control object is supplied, the parameters from it will be used. If parameters are passed also in the invocation statement, they will override the corresponding elements of the control object. |

## **Details**

This function computes the minimum regularized covariance determinant estimator (MRCD) of location and scatter and returns an S4 object of class CovMrcd-class containing the estimates. Similarly like the MCD method, MRCD looks for the h(>n/2) observations (out of n) whose classical covariance matrix has the lowest possible determinant, but replaces the subset-based covariance by a regularized covariance estimate, defined as a weighted average of the sample covariance of the h-subset and a predetermined positive definite target matrix. The Minimum Regularized Covariance Determinant (MRCD) estimator is then the regularized covariance based on the h-subset which makes the overall determinant the smallest. A data-driven procedure sets the weight of the target matrix (rho), so that the regularization is only used when needed.

## Value

An S4 object of class CovMrcd-class which is a subclass of the virtual class CovRobust-class.

50 CovMrcd

CovMrcd-class

MRCD Estimates of Multivariate Location and Scatter

# Description

This class, derived from the virtual class "CovRobust" accommodates MRCD Estimates of multivariate location and scatter computed by a variant of the 'Fast MCD' algorithm.

### **Objects from the Class**

Objects can be created by calls of the form new("CovMrcd", ...), but the usual way of creating CovMrcd objects is a call to the function CovMrcd which serves as a constructor.

52 CovMrcd-class

# **Slots**

alpha: Object of class "numeric" - the size of the subsets over which the determinant is minimized (the default is (n+p+1)/2)

quan: Object of class "numeric" - the number of observations on which the MCD is based. If quan equals n.obs, the MCD is the classical covariance matrix.

best: Object of class "Uvector" - the best subset found and used for computing the raw estimates. The size of best is equal to quan

cnp2: Object of class "numeric" - containing the consistency correction factor of the estimate of the covariance matrix.

icov: The inverse of the covariance matrix.

rho: The estimated regularization parameter.

target: The estimated target matrix.

crit: from the "CovRobust" class.

call, cov, center, n. obs, mah, method, X: from the "Cov" class.

### **Extends**

```
Class "CovRobust", directly. Class "Cov", by class "CovRobust".
```

### Methods

No methods defined with class "CovMrcd" in the signature.

| CovMve | Robust Location and Scatter Estimation via MVE |  |
|--------|--|--|

53

## **Description**

Computes a robust multivariate location and scatter estimate with a high breakdown point, using the 'MVE' (Minimum Volume Ellipsoid) estimator.

## Usage

```
CovMve(x, alpha = 1/2, nsamp = 500, seed = NULL, trace = FALSE, control)
```

## **Arguments**

| x       | a matrix or data frame.  |
|---------|--|
| alpha   | numeric parameter controlling the size of the subsets over which the determinant is minimized, i.e., alpha*n observations are used for computing the determinant. Allowed values are between 0.5 and 1 and the default is 0.5.   |
| nsamp   | number of subsets used for initial estimates or "best" or "exact". Default is nsamp = 500. For nsamp="best" exhaustive enumeration is done, as long as the number of trials does not exceed 5000. For "exact", exhaustive enumeration will be attempted however many samples are needed. In this case a warning message will be displayed saying that the computation can take a very long time. |
| seed    | starting value for random generator. Default is seed = NULL  |
| trace   | whether to print intermediate results. Default is trace = FALSE  |
| control | a control object (S4) of class CovControlMve-class containing estimation options - same as these provided in the fucntion specification. If the control object is supplied, the parameters from it will be used. If parameters are passed also in the invocation statement, they will override the corresponding elements of the control object.   |

### **Details**

This function computes the minimum volume ellipsoid estimator of location and scatter and returns an S4 object of class CovMve-class containing the estimates.

The approximate estimate is based on a subset of size alpha\*n with an enclosing ellipsoid of smallest volume. The mean of the best found subset provides the raw estimate of the location, and the rescaled covariance matrix is the raw estimate of scatter. The rescaling of the raw covariance matrix is by median(dist)/qchisq(0.5, p) and this scale factor is returned in the slot raw.cnp2. Currently no finite sample corrction factor is applied. The Mahalanobis distances of all observations from the location estimate for the raw covariance matrix are calculated, and those points within the 97.5 under Gaussian assumptions are declared to be good. The final (reweightd) estimates are the mean and rescaled covariance of the good points. The reweighted covariance matrix is rescaled by 1/pgamma(qchisq(alpha, p)/2, p/2 + 1)/alpha (see Croux and Haesbroeck, 1999) and this scale factor is returned in the slot cnp2.

54 CovMve

The search for the approximate solution is made over ellipsoids determined by the covariance matrix of p+1 of the data points and applying a simple but effective improvement of the subsampling procedure as described in Maronna et al. (2006), p. 198. Although there exists no formal proof of this improvement (as for MCD and LTS), simulations show that it can be recommended as an approximation of the MVE.

## Value

An S4 object of class CovMve-class which is a subclass of the virtual class CovRobust-class.

#### Note

Main reason for implementing the MVE estimate was that it is the recommended initial estimate for S estimation (see Maronna et al. (2006), p. 199) and will be used by default in CovMest (after removing the correction factors from the covariance matrix and rescaling to determinant 1).

CovMve-class

MVE Estimates of Multivariate Location and Scatter

# **Description**

This class, derived from the virtual class "CovRobust" accommodates MVE Estimates of multivariate location and scatter computed by the 'Fast MVE' algorithm.

## **Objects from the Class**

Objects can be created by calls of the form new("CovMve", ...), but the usual way of creating CovMve objects is a call to the function CovMve which serves as a constructor.

### **Slots**

- alpha: Object of class "numeric" the size of the subsets over which the volume of the ellipsoid is minimized (the default is (n+p+1)/2)
- quan: Object of class "numeric" the number of observations on which the MVE is based. If quan equals n.obs, the MVE is the classical covariance matrix.
- best: Object of class "Uvector" the best subset found and used for computing the raw estimates.

  The size of best is equal to quan
- raw.cov: Object of class "matrix" the raw (not reweighted) estimate of location
- raw.center: Object of class "vector" the raw (not reweighted) estimate of scatter
- raw.mah: Object of class "Uvector" mahalanobis distances of the observations based on the raw estimate of the location and scatter
- raw.wt: Object of class "Uvector" weights of the observations based on the raw estimate of the location and scatter
- raw.cnp2: Object of class "numeric" a vector of length two containing the consistency correction factor and the finite sample correction factor of the raw estimate of the covariance matrix
- cnp2: Object of class "numeric" a vector of length two containing the consistency correction factor and the finite sample correction factor of the final estimate of the covariance matrix.

```
iter, crit, wt: from the "CovRobust" class.
```

call, cov, center, n. obs, mah, method, singularity, X: from the "Cov" class.

CovOgk Robust Location and Scatter Estimation - Ortogonalized Gnanadesikan-Kettenring (OGK)

## **Description**

Computes a robust multivariate location and scatter estimate with a high breakdown point, using the pairwise algorithm proposed by Marona and Zamar (2002) which in turn is based on the pairwise robust estimator proposed by Gnanadesikan-Kettenring (1972).

## Usage

```
CovOgk(x, niter = 2, beta = 0.9, control)
```

## **Arguments**

x a matrix or data frame.

niter number of iterations, usually 1 or 2 since iterations beyond the second do not

lead to improvement.

beta coverage parameter for the final reweighted estimate

control a control object (S4) of class CovControlOgk-class containing estimation op-

tions - same as these provided in the function specification. If the control object is supplied, the parameters from it will be used. If parameters are passed also in the invocation statement, they will override the corresponding elements of the control object. The control object contains also functions for computing the robust univariate location and dispersion estimate mrob and for computing the

robust estimate of the covariance between two random variables vrob.

CovOgk 57

### **Details**

The method proposed by Marona and Zamar (2002) allowes to obtain positive-definite and almost affine equivariant robust scatter matrices starting from any pairwise robust scatter matrix. The default robust estimate of covariance between two random vectors used is the one proposed by Gnanadesikan and Kettenring (1972) but the user can choose any other method by redefining the function in slot vrob of the control object CovControlOgk. Similarly, the function for computing the robust univariate location and dispersion used is the tau scale defined in Yohai and Zamar (1998) but it can be redefined in the control object.

The estimates obtained by the OGK method, similarly as in CovMcd are returned as 'raw' estimates. To improve the estimates a reweighting step is performed using the coverage parameter beta and these reweighted estimates are returned as 'final' estimates.

#### Value

An S4 object of class CovOgk-class which is a subclass of the virtual class CovRobust-class.

#### Note

If the user does not specify a scale and covariance function to be used in the computations or specifies one by using the arguments smrob and svrob (i.e. the names of the functions as strings), a native code written in C will be called which is by far faster than the R version.

If the arguments mrob and vrob are not NULL, the specified functions will be used via the pure R implementation of the algorithm. This could be quite slow.

See CovControlOgk for details.

CovOgk-class

OGK Estimates of Multivariate Location and Scatter

## **Description**

This class, derived from the virtual class "CovRobust" accommodates OGK Estimates of multivariate location and scatter computed by the algorithm proposed by Marona and Zamar (2002).

## **Objects from the Class**

Objects can be created by calls of the form new("CovOgk", ...), but the usual way of creating CovOgk objects is a call to the function CovOgk which serves as a constructor.

# **Slots**

raw.cov: Object of class "matrix" the raw (not reweighted) estimate of covariance matrix raw.center: Object of class "vector" - the raw (not reweighted) estimate of the location vector raw.mah: Object of class "Uvector" - mahalanobis distances of the observations based on the raw estimate of the location and scatter

CovRobust 59

```
raw.wt: Object of class "Uvector" - weights of the observations based on the raw estimate of the
    location and scatter

iter, crit, wt: from the "CovRobust" class.

call, cov, center, n.obs, mah, method, singularity, X: from the "Cov" class.
```

#### **Extends**

```
Class "CovRobust", directly. Class "Cov", by class "CovRobust".
```

## Methods

No methods defined with class "CovOgk" in the signature.

## Author(s)

CovRobust

Robust Location and Scatter Estimation

# **Description**

Computes a robust multivariate location and scatter estimate with a high breakdown point, using one of the available estimators.

## Usage

```
CovRobust(x, control, na.action = na.fail)
```

60 CovRobust

## **Arguments**

x a matrix or data frame.

control a control object (S4) for one of the available control classes, e.g. CovControlMcd-class,

CovControlOgk-class, CovControlSest-class, etc., containing estimation options. The class of this object defines which estimator will be used. Alternatively a character string can be specified which names the estimator - one of auto, sde, mcd, ogk, m, mve, sfast, surreal, bisquare, rocke. If 'auto' is specified or the argument is missing, the function will select the estimator (see below for

details)

na.action A function to specify the action to be taken if missing values are found. The

default action is for the procedure to fail. An alternative is na.omit, which leads

to rejection of cases with missing values on any required variable.

#### **Details**

This function simply calls the restimate method of the control object control. If a character string naming an estimator is specified, a new control object will be created and used (with default estimation options). If this argument is missing or a character string 'auto' is specified, the function will select the robust estimator according to the size of the dataset. If there are less than 1000 observations and less than 10 variables or less than 5000 observations and less than 5 variables, Stahel-Donoho estimator will be used. Otherwise, if there are less than 50000 observations either bisquare S-estimates (for less than 10 variables) or Rocke type S-estimates (for 10 to 20 variables) will be used. In both cases the S iteration starts at the initial MVE estimate. And finally, if there are more than 50000 observations and/or more than 20 variables the Orthogonalized Quadrant Correlation estimator (CovOgk with the corresponding parameters) is used.

## Value

An object derived from a CovRobust object, depending on the selected estimator.

CovRobust-class 61

|  | "CovRobust" - virtual base class for robust estimates of multi-<br>e location and scatter |
|--|---|
|--|---|

## **Description**

CovRobust is a virtual base class used for deriving the concrete classes representing different robust estimates of multivariate location and scatter. Here are implemeted the standard methods common for all robust estimates like show, summary and plot. The derived classes can override these methods and can define new ones.

# **Objects from the Class**

A virtual Class: No objects may be created from it.

### Slots

```
iter: number of iterations used to compute the estimates
crit: value of the criterion function
wt: weights
call, cov, center, n.obs, mah, method, singularity, X: from the "Cov" class.
```

# **Extends**

```
Class "Cov", directly.
```

## Methods

# **Examples**

CovSde

Stahel-Donoho Estimates of Multivariate Location and Scatter

# Description

Compute a robust estimate of location and scale using the Stahel-Donoho projection based estimator

## Usage

```
CovSde(x, nsamp, maxres, tune = 0.95, eps = 0.5, prob = 0.99, seed = NULL, trace = FALSE, control)
```

# Arguments

| 2 | X      | a matrix or data frame.   |
|---|--------|---|
| ı | nsamp  | a positive integer giving the number of resamples required; nsamp may not be reached if too many of the p-subsamples, chosen out of the observed vectors, are in a hyperplane. If $nsamp = \emptyset$ all possible subsamples are taken. If $nsamp$ is omitted, it is calculated to provide a breakdown point of eps with probability prob. |
| ı | maxres | a positive integer specifying the maximum number of resamples to be performed including those that are discarded due to linearly dependent subsamples. If maxres is omitted it will be set to 2 times nsamp.  |
|   | tune   | a numeric value between 0 and 1 giving the fraction of the data to receive non-zero weight. Defaults to $0.95$  |
| ı | prob   | a numeric value between 0 and 1 specifying the probability of high breakdown point; used to compute nsamp when nsamp is omitted. Defaults to 0.99.  |
| ( | eps    | a numeric value between 0 and 0.5 specifying the breakdown point; used to compute nsamp when nresamp is omitted. Defaults to 0.5.   |
| : | seed   | starting value for random generator. Default is seed = NULL.  |
|   | trace  | whether to print intermediate results. Default is trace = FALSE.  |
|   |        |   |

CovSde 63

control

a control object (S4) of class CovControlSde-class containing estimation options - same as these provided in the fucntion specification. If the control object is supplied, the parameters from it will be used. If parameters are passed also in the invocation statement, they will override the corresponding elements of the control object.

#### **Details**

The projection based Stahel-Donoho estimator posses very good statistical properties, but it can be very slow if the number of variables is too large. It is recommended to use this estimator if n <= 1000 and p<=10 or n <= 5000 and p<=5. The number of subsamples required is calculated to provide a breakdown point of eps with probability prob and can reach values larger than the larger integer value - in such case it is limited to .Machine\$integer.max. Of course you could provide nsamp in the call, i.e. nsamp=1000 but this will not guarantee the required breakdown point of th eestimator. For larger data sets it is better to use CovMcd or CovOgk. If you use CovRobust, the estimator will be selected automatically according on the size of the data set.

### Value

An S4 object of class CovSde-class which is a subclass of the virtual class CovRobust-class.

### Note

The Fortran code for the Stahel-Donoho method was taken almost with no changes from package robust which in turn has it from the *Insightful Robust Library* (thanks to by Kjell Konis).

CovSest

S Estimates of Multivariate Location and Scatter

# **Description**

Computes S-Estimates of multivariate location and scatter based on Tukey's biweight function using a fast algorithm similar to the one proposed by Salibian-Barrera and Yohai (2006) for the case of regression. Alternativley, the Ruppert's SURREAL algorithm, bisquare or Rocke type estimation can be used.

# Usage

```
CovSest(x, bdp = 0.5, arp = 0.1, eps = 1e-5, maxiter = 120,
    nsamp = 500, seed = NULL, trace = FALSE, tolSolve = 1e-14,
    scalefn, maxisteps=200,
    initHsets = NULL, save.hsets = missing(initHsets) || is.null(initHsets),
    method = c("sfast", "surreal", "bisquare", "rocke", "suser", "sdet"),
    control, t0, S0, initcontrol)
```

## **Arguments**

| X        | a matrix or data frame.  |
|----------|--|
| bdp      | a numeric value specifying the required breakdown point. Allowed values are between $(n - p)/(2 * n)$ and 1 and the default is bdp=0.5.  |
| arp      | a numeric value specifying the asympthotic rejection point (for the Rocke type S estimates), i.e. the fraction of points receiving zero weight (see Rocke (1996)). Default is arp=0.1.                               |
| eps      | a numeric value specifying the relative precision of the solution of the S-estimate (bisquare and Rocke type). Default is to eps=1e-5.   |
| maxiter  | maximum number of iterations allowed in the computation of the S-estimate (bisquare and Rocke type). Default is maxiter=120.   |
| nsamp    | the number of random subsets considered. The default is different for the different methods: (i) for sfast it is nsamp = 20, (ii) for surreal it is nsamp = 600*p and (iii) for bisquare or rocke it is nsamp = 500. |
| seed     | starting value for random generator. Default is seed = NULL.   |
| trace    | whether to print intermediate results. Default is trace = FALSE.   |
| tolSolve | numeric tolerance to be used for inversion (solve) of the covariance matrix in mahalanobis.  |

66 CovSest

| scalefn     | function to compute a robust scale estimate or character string specifying a rule determining such a function. Used for computing the "deterministic" Sestimates (method="sdet"). If scalefn is missing or is NULL, the function is selected depending on the data set size, following the recomendation of Hubert et al. (2012) - Qn if n <= 1000 and scaleTau2 otherwise. |
|-------------|---|
| maxisteps   | maximal number of concentration steps in the deterministic S-estimates; should not be reached.  |
| initHsets   | NULL or a $Kxn$ integer matrix of initial subsets of observations of size (specified by the indices in 1:n).  |
| save.hsets  | (for deterministic S-estimates) logical indicating if the initial subsets should be returned as initHsets.  |
| method      | Which algorithm to use: 'sfast'=C implementation of FAST-S, 'surreal'=SURREAL, 'bisquare', 'rocke'. The method 'suser' currently calls the R implementation of FAST-S but in the future will allow the user to supply own rho function. The method 'sdet' invokes the deterministic algorithm of Hubert et al. (2012).  |
| control     | a control object (S4) of class CovControlSest-class containing estimation options - same as these provided in the fucntion specification. If the control object is supplied, the parameters from it will be used. If parameters are passed also in the invocation statement, they will override the corresponding elements of the control object.                           |
| t0          | optional initial HBDP estimate for the center   |
| SØ          | optional initial HBDP estimate for the covariance matrix  |
| initcontrol | optional control object to be used for computing the initial HBDP estimates   |
|             |   |

## **Details**

Computes multivariate S-estimator of location and scatter. The computation will be performed by one of the following algorithms:

**FAST-S** An algorithm similar to the one proposed by Salibian-Barrera and Yohai (2006) for the case of regression

SURREAL Ruppert's SURREAL algorithm when method is set to 'surreal'

BISQUARE Bisquare S-Estimate with method set to 'bisquare'

ROCKE Rocke type S-Estimate with method set to 'rocke'

Except for the last algorithm, *ROCKE*, all other use Tukey biweight loss function. The tuning parameters used in the loss function (as determined by bdp) are returned in the slots cc and kp of the result object. They can be computed by the internal function .csolve.bw.S(bdp, p).

# Value

An S4 object of class CovSest-class which is a subclass of the virtual class CovRobust-class.

diabetes

Reaven and Miller diabetes data

## Description

The data set contains five measurements made on 145 non-obese adult patients classified into three groups.

The three primary variables are glucose intolerance (area under the straight line connecting glucose levels), insulin response to oral glucose (area under the straight line connecting insulin levels) and insulin resistance (measured by the steady state plasma glucose (SSPG) determined after chemical suppression of endogenous insulin secretion). Two additional variables, the relative weight and fasting plasma glucose, are also included.

Reaven and Miller, following Friedman and Rubin (1967), applied cluster analysis to the three primary variables and identified three clusters: "normal", "chemical diabetic", and "overt diabetic" subjects. The column group contains the classifications of the subjects into these three groups, obtained by current medical criteria.

### Usage

```
data(diabetes)
```

### Format

A data frame with the following variables:

**rw** relative weight, expressed as the ratio of actual weight to expected weight, given the person's height.

**fpg** fasting plasma glucose level.

**glucose** area under plasma glucose curve after a three hour oral glucose tolerance test (OGTT).

insulin area under plasma insulin curve after a three hour oral glucose tolerance test (OGTT).

sspg Steady state plasma glucose, a measure of insulin resistance.

**group** the type of diabetes: a factor with levels normal, chemical and overt.

fish

Fish Catch Data Set

### Description

The Fish Catch data set contains measurements on 159 fish caught in the lake Laengelmavesi, Finland.

# Usage

```
data(fish)
```

# Format

A data frame with 159 observations on the following 7 variables.

Weight Weight of the fish (in grams)

Length1 Length from the nose to the beginning of the tail (in cm)

Length2 Length from the nose to the notch of the tail (in cm)

Length3 Length from the nose to the end of the tail (in cm)

Height Maximal height as % of Length3

Width Maximal width as % of Length3

Species Species

fish 71

### **Details**

The Fish Catch data set contains measurements on 159 fish caught in the lake Laengelmavesi, Finland. For the 159 fishes of 7 species the weight, length, height, and width were measured. Three different length measurements are recorded: from the nose of the fish to the beginning of its tail, from the nose to the notch of its tail and from the nose to the end of its tail. The height and width are calculated as percentages of the third length variable. This results in 6 observed variables, Weight, Length1, Length2, Length3, Height, Width. Observation 14 has a missing value in variable Weight, therefore this observation is usually excluded from the analysis. The last variable, Species, represents the grouping structure: the 7 species are 1=Bream, 2=Whitewish, 3=Roach, 4=Parkki, 5=Smelt, 6=Pike, 7=Perch. This data set was also analyzed in the context of robust Linear Discriminant Analysis by Todorov (2007), Todorov and Pires (2007).

72 fruit

fruit

Fruit data set

## **Description**

A data set that contains the spectra of six different cultivars of the same fruit (cantaloupe - *Cucumis melo* L. Cantaloupensis group) obtained from Colin Greensill (Faculty of Engineering and Physical Systems, Central Queensland University, Rockhampton, Australia). The total data set contained 2818 spectra measured in 256 wavelengths. For illustrative purposes are considered only three cultivars out of it, named D, M and HA with sizes 490, 106 and 500, respectively. Thus the data set thus contains 1096 observations. For more details about this data set see the references below.

## Usage

data(fruit)

### **Format**

A data frame with 1096 rows and 257 variables (one grouping variable – cultivar – and 256 measurement variables).

### Source

Colin Greensill (Faculty of Engineering and Physical Systems, Central Queensland University, Rockhampton, Australia).

getCenter-methods 73

getCenter-methods

Accessor methods to the essential slots of Cov and its subclasses

### **Description**

Accessor methods to the slots of objects of classCov and its subclasses

## Usage

```
getCenter(obj)
getCov(obj)
getCorr(obj)
getData(obj)
getDistance(obj)
getEvals(obj)
getDet(obj)
getShape(obj)
getFlag(obj, prob=0.975)
getMeth(obj)
isClassic(obj)
getRaw(obj)
```

## **Arguments**

obj an object of class "Cov" or of a class derived from "Cov" prob optional argument for getFlag - probability, defaults to 0.975

## Methods

```
\begin{tabular}{ll} \textbf{obj} = "\textbf{Cov"} & generic functions - see getCenter, getCov, getCorr, getData, getDistance, getEvals, getDet, getShape, getFlag, isClassic \\ \end{tabular}
```

obj = "CovRobust" generic functions - see getCenter, getCov, getCorr, getData, getDistance,
 getEvals, getDet, getShape, getFlag, getMeth, isClassic

getEllipse

Calculates the points for drawing a confidence ellipsoid

### **Description**

A simple function to calculate the points of a confidence ellipsoid, by default dist=qchisq(0.975, 2)

## Usage

```
getEllipse(loc = c(0, 0), cov = matrix(c(1, 0, 0, 1), ncol = 2), crit = 0.975)
```

74 getLoadings-methods

## **Arguments**

loc location vector

cov a pXp covariance matrix

crit the confidence level, default is crit=0.975

### Value

A matrix with two columns containing the calculated points.

## Author(s)

Valentin Todorov, <valentin.todorov@chello.at>

## **Examples**

getLoadings-methods

Accessor methods to the essential slots of Pca and its subclasses

# Description

Accessor methods to the slots of objects of class Pca and its subclasses

## Arguments

```
obj an object of class "Pca" or of a class derived from "Pca"
```

## Methods

```
    obj = "Pca" Accessors for object of class Pca
    obj = "PcaRobust" Accessors for object of class PcaRobust
    obj = "PcaClassic" Accessors for object of class PcaClassic
```

hemophilia 75

hemophilia

Hemophilia Data

## **Description**

The hemophilia data set contains two measured variables on 75 women, belonging to two groups: n1=30 of them are non-carriers (normal group) and n2=45 are known hemophilia A carriers (obligatory carriers).

### Usage

data(hemophilia)

#### **Format**

A data frame with 75 observations on the following 3 variables.

AHFactivity AHF activity

AHFantigen AHF antigen

gr group - normal or obligatory carrier

### **Details**

Originally analized in the context of discriminant analysis by Habemma and Hermans (1974). The objective is to find a procedure for detecting potential hemophilia A carriers on the basis of two measured variables: X1=log10(AHV activity) and X2=log10(AHV-like antigen). The first group of n1=30 women consists of known non-carriers (normal group) and the second group of n2=45 women is selected from known hemophilia A carriers (obligatory carriers). This data set was also analyzed by Johnson and Wichern (1998) as well as, in the context of robust Linear Discriminant Analysis by Hawkins and McLachlan (1997) and Hubert and Van Driessen (2004).

```

ionosphere

Johns Hopkins University Ionosphere database.

# Description

"This radar data was collected by a system in Goose Bay, Labrador. This system consists of a phased array of 16 high-frequency antennas with a total transmitted power on the order of 6.4 kilowatts. The targets were free electrons in the ionosphere. "good" radar returns are those showing evidence of some type of structure in the ionosphere. "bad" returns are those that do not; their signals pass through the ionosphere. Received signals were processed using an autocorrelation function whose arguments are the time of a pulse and the pulse number. There were 17 described by 2 attributes per pulse number, corresponding to the complex values returned by the function resulting from the complex electromagnetic signal." [UCI archive]

## Usage

```
data(ionosphere)
```

## **Format**

A data frame with 351 rows and 33 variables: 32 measurements and one (the last, Class) grouping variable: 225 'good' and 126 'bad'.

The original dataset at UCI contains 351 rows and 35 columns. The first 34 columns are features, the last column contains the classification label of 'g' and 'b'. The first feature is binary and the second one is only 0s, one grouping variable - factor with labels 'good' and 'bad'.

## Source

78 Lda-class

Lda-class

Class "Lda" - virtual base class for all classic and robust LDA classes

## **Description**

The class Lda serves as a base class for deriving all other classes representing the results of classical and robust Linear Discriminant Analisys methods

# **Objects from the Class**

A virtual Class: No objects may be created from it.

## **Slots**

call: the (matched) function call.

prior: prior probabilities used, default to group proportions

counts: number of observations in each class

center: the group means

cov: the common covariance matrix

1df: a matrix containing the linear discriminant functions

1dfconst: a vector containing the constants of each linear discriminant function

method: a character string giving the estimation method used

X: the training data set (same as the input parameter x of the constructor function)

grp: grouping variable: a factor specifying the class for each observation.

covobj: object of class "Cov" containing the estimate of the common covariance matrix of the centered data. It is not NULL only in case of method "B".

control: object of class "CovControl" specifying which estimate and with what estimation options to use for the group means and common covariance (or NULL for classical linear discriminant analysis)

#### Methods

predict signature(object = "Lda"): calculates prediction using the results in object. An optional data frame or matrix in which to look for variables with which to predict. If omitted, the training data set is used. If the original fit used a formula or a data frame or a matrix with column names, newdata must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

```
show signature(object = "Lda"): prints the results
summary signature(object = "Lda"): prints summary information
```

LdaPP

Robust Linear Discriminant Analysis by Projection Pursuit

## **Description**

Performs robust linear discriminant analysis by the projection-pursuit approach - proposed by Pires and Branco (2010) - and returns the results as an object of class LdaPP (aka constructor).

# Usage

82 LdaPP

### **Arguments**

| formula   | a formula of the form $y^x$ , it describes the response and the predictors. The formula can be more complicated, such as $y^2\log(x)+z$ etc (see formula for more details). The response should be a factor representing the response variable, or any vector that can be coerced to such (such as a logical variable). |
|-----------|---|
| data      | an optional data frame (or similar: see model.frame) containing the variables in the formula formula.   |
| subset    | an optional vector used to select rows (observations) of the data matrix x.   |
| na.action | a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The default is na.omit.   |
| X         | a matrix or data frame containing the explanatory variables (training set).   |
| grouping  | grouping variable: a factor specifying the class for each observation.  |
| prior     | prior probabilities, default to the class proportions for the training set.   |
| tol       | tolerance   |
| method    | method  |
| optim     | wheather to perform the approximation using the Nelder and Mead simplex method (see function optim() from package stats). Default is optim = FALSE  |
| trace     | whether to print intermediate results. Default is trace = FALSE.  |
|           | arguments passed to or from other methods.  |

## **Details**

Currently the algorithm is implemented only for binary classification and in the following will be assumed that only two groups are present.

The PP algorithm searches for low-dimensional projections of higher-dimensional data where a projection index is maximized. Similar to the original Fisher's proposal the squared standardized distance between the observations in the two groups is maximized. Instead of the sample univariate mean and standard deviation (T,S) robust alternatives are used. These are selected through the argument method and can be one of

huber the pair (T,S) are the robust M-estimates of location and scale
mad (T,S) are the Median and the Median Absolute Deviation
sest the pair (T,S) are the robust S-estimates of location and scale
class (T,S) are the mean and the standard deviation.

The first approximation AI to the solution is obtained by investigating a finite number of candidate directions, the unit vectors defined by all pairs of points such that one belongs to the first group and the other to the second group. The found solution is stored in the slots raw.ldf and raw.ldfconst.

The second approximation A2 (optional) is performed by a numerical optimization algorithm using AI as initial solution. The Nelder and Mead method implemented in the function optim is applied. Whether this refinement will be used is controlled by the argument optim. If optim=TRUE the result of the optimization is stored into the slots ldf and ldfconst. Otherwise these slots are set equal to raw.ldf and raw.ldfconst.

LdaPP 83

## Value

Returns an S4 object of class LdaPP-class

## Warning

Still an experimental version! Only binary classification is supported.

LdaPP-class

Class "LdaPP" - Robust method for Linear Discriminant Analysis by Projection-pursuit

## **Description**

The class LdaPP represents an algorithm for robust linear discriminant analysis by projection-pursuit approach. The objects of class LdaPP contain the results of the robust linear discriminant analysis by projection-pursuit approach.

# **Objects from the Class**

Objects can be created by calls of the form new("LdaPP", . . . ) but the usual way of creating LdaPP objects is a call to the function LdaPP which serves as a constructor.

## **Slots**

```
call: The (matched) function call.
prior: Prior probabilities used, default to group proportions
counts: number of observations in each class
center: the group means
```

LdaPP-class 85

cov: the common covariance matrix

raw.ldf: a matrix containing the raw linear discriminant functions - see Details in LdaPP

raw.ldfconst: a vector containing the raw constants of each raw linear discriminant function - see Details in LdaPP

1df: a matrix containing the linear discriminant functions

ldfconst: a vector containing the constants of each linear discriminant function

method: a character string giving the estimation method used

X: the training data set (same as the input parameter x of the constructor function)

grp: grouping variable: a factor specifying the class for each observation.

### **Extends**

Class "LdaRobust", directly. Class "Lda", by class "LdaRobust", distance 2.

### Methods

predict signature(object = "LdaPP"): calculates prediction using the results in object. An optional data frame or matrix in which to look for variables with which to predict. If omitted, the training data set is used. If the original fit used a formula or a data frame or a matrix with column names, newdata must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order. If the argument raw=TRUE is set the raw (obtained by the first approximation algorithm) linear discriminant function and constant will be used.

Linda

Robust Linear Discriminant Analysis

# Description

Robust linear discriminant analysis based on MCD and returns the results as an object of class Linda (aka constructor).

# Usage

## **Arguments**

| x           | a matrix or data frame containing the explanatory variables (training set).   |
|-------------|---|
| grouping    | grouping variable: a factor specifying the class for each observation.  |
| prior       | prior probabilities, default to the class proportions for the training set.   |
| tol         | tolerance   |
| method      | method  |
| alpha       | this parameter measures the fraction of outliers the algorithm should resist. In MCD alpha controls the size of the subsets over which the determinant is minimized, i.e. alpha*n observations are used for computing the determinant. Allowed values are between 0.5 and 1 and the default is 0.5. |
| 11med       | whether to use L1 median (space median) instead of MCD to compute the group means locations in order to center the data in methods mcdB and mcdC. useful in case of groups with small size. Default is 11med = FALSE.   |
| cov.control | specifies which covariance estimator to use by providing a CovControl-class object. The default is CovControlMcd-class which will indirectly call CovMcd. If cov.control=NULL is specified, the classical estimates will be used by calling CovClassic  |
| •           |   |
| trace       | whether to print intermediate results. Default is trace = FALSE.  |

Linda-class

Class "Linda" - Robust method for LINear Discriminant Analysis

## **Description**

Robust linear discriminant analysis is performed by replacing the classical group means and withing group covariance matrix by robust equivalents based on MCD.

## **Objects from the Class**

Objects can be created by calls of the form new("Linda", ...) but the usual way of creating Linda objects is a call to the function Linda which serves as a constructor.

## **Slots**

```
call: The (matched) function call.

prior: Prior probabilities used, default to group proportions

counts: number of observations in each class

center: the group means

cov: the common covariance matrix

ldf: a matrix containing the linear discriminant functions

ldfconst: a vector containing the constants of each linear discriminant function

method: a character string giving the estimation method used

X: the training data set (same as the input parameter x of the constructor function)

grp: grouping variable: a factor specifying the class for each observation.

l1med: wheather L1 median was used to compute group means.
```

90 Imom32

## **Extends**

```
Class "LdaRobust", directly. Class "Lda", by class "LdaRobust", distance 2.
```

### Methods

No methods defined with class "Linda" in the signature.

1mom32

Hosking and Wallis Data Set, Table 3.2

## **Description**

The data on annual maximum streamflow at 18 sites with smallest drainage area basin in south-eastern USA contains the sample L-moments ratios (L-CV, L-skewness and L-kurtosis) as used by Hosking and Wallis (1997) to illustrate the discordancy measure in regional frequency analysis (RFA).

### Usage

```
data(lmom32)
```

#### **Format**

A data frame with 18 observations on the following 3 variables.

L-CV L-coefficient of variation

L-skewness L-coefficient of skewness

L-kurtosis L-coefficient of kurtosis

lmom33 91

### **Details**

The sample L-moment ratios (L-CV, L-skewness and L-kurtosis) of a site are regarded as a point in three dimensional space.

Computer Hardware

### Description

A data set containing relative CPU performance data of 209 machines on 8 variables. are predictive, one (PRP) is the goal field and one (ERP) is the linear regression's guess. The estimated relative performance values were estimated by the authors using a linear regression method. See their article (Ein-Dor and Feldmesser, CACM 4/87, pp 308-317) for more details on how the relative performance values were set.

# Usage

data(machines)

### **Format**

A data frame with 209 rows and 8 variables The variables are as follows:

- MMIN: minimum main memory in kilobytes (integer)
- MMAX: maximum main memory in kilobytes (integer)
- CACH: cache memory in kilobytes (integer)
- CHMIN: minimum channels in units (integer)
- CHMAX: maximum channels in units (integer)
- PRP: published relative performance (integer)
- ERP: estimated relative performance from the original article (integer)

Marona and Yohai Artificial Data

## **Description**

Simple artificial data set generated according the example by Marona and Yohai (1998). The data set consists of 20 bivariate normal observations generated with zero means, unit variances and correlation 0.8. The sample correlation is 0.81. Two outliers are introduced (i.e. these are 10% of the data) in the following way: two points are modified by interchanging the largest (observation 19) and smallest (observation 9) value of the first coordinate. The sample correlation becomes 0.05. This example provides a good example of the fact that a multivariate outlier need not be an outlier in any of its coordinate variables.

### Usage

data(maryo)

#### **Format**

A data frame with 20 observations on 2 variables. To introduce the outliers x[9,1] with x[19,1] are interchanged.

octane 95

### **Examples**

```
data(maryo)
getCorr(CovClassic(maryo))
                                      ## the sample correlation is 0.81
## Modify 10%% of the data in the following way:
## modify two points (out of 20) by interchanging the
## largest and smallest value of the first coordinate
imin <- which(maryo[,1]==min(maryo[,1]))</pre>
imax <- which(maryo[,1]==max(maryo[,1]))</pre>
                                                  \# imax = 19
maryo1 <- maryo
maryo1[imin,1] <- maryo[imax,1]</pre>
maryo1[imax,1] <- maryo[imin,1]</pre>
## The sample correlation becomes 0.05
plot(maryo1)
getCorr(CovClassic(maryo1))
                                      ## the sample correlation becomes 0.05
getCorr(CovMcd(maryo1))
                              ## the (reweighted) MCD correlation is 0.79
```

octane

Octane data

## **Description**

The octane data contains near infrared absorbance spectra (NIR) of n=39 gasoline samples over p=226 wavelengths ranging from 1102 nm to 1552 nm with measurements every two nanometers. For each of the 39 production gasoline samples the octane number y was measured. Six of the samples (25, 26, and 36-39) contain added alcohol.

## Usage

```
data(octane)
```

### **Format**

A data frame with 39 observations and 227 columns, the wavelengts are by column and the first variable is the dependent one (y).

Olive Oil Data

# **Description**

This dataset consists of 120 olive oil samples on measurements on 25 chemical compositions (fatty acids, sterols, triterpenic alcohols) of olive oils from Tuscany, Italy (Armanino et al. 1989). There are 4 classes corresponding to different production areas. Class 1, Class 2, Class 3, and Class 4 contain 50, 25, 34, and 11 observations, respectively.

## Usage

```
data(olitos)
```

### **Format**

A data frame with 120 observations on the following 26 variables.

- X1 Free fatty acids
- X2 Refractive index
- X3 K268
- X4 delta K
- X5 Palmitic acid
- X6 Palmitoleic acid

#### **Details**

Samples of different plant species were collected along a 120 km transect running through the city of Oslo, Norway (forty samples each of leaves, needles, roots or barks of several plant species), and the concentrations of 25 chemical elements for the sample materials are reported. The factors that influenced the observed element concentrations in the sample materials were investigated. This data set was used in Todorov and Filzmoser (2007) for illustration of the robust statistics for one-way MANOVA implemented in the function Wilks.test.

```

Pca-class

Class "Pca" - virtual base class for all classic and robust PCA classes

## **Description**

The class Pca searves as a base class for deriving all other classes representing the results of the classical and robust Principal Component Analisys methods

# **Objects from the Class**

A virtual Class: No objects may be created from it.

## **Slots**

```
call: Object of class "language"
center: Object of class "vector" the center of the data
scale: Object of class "vector" the scaling applied to each variable of the data
rank: Object of class "numeric" the rank of the data matrix
loadings: Object of class "matrix" the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors)
eigenvalues: Object of class "vector" the eigenvalues
```

```
scores: Object of class "matrix" the scores - the value of the projected on the space of the principal components data (the centred (and scaled if requested) data multiplied by the loadings matrix) is returned. Hence, cov(scores) is the diagonal matrix diag(eigenvalues)
```

k: Object of class "numeric" number of (choosen) principal components

sd: Object of class "Uvector" Score distances within the robust PCA subspace

od: Object of class "Uvector" Orthogonal distances to the robust PCA subspace

cutoff.sd: Object of class "numeric" Cutoff value for the score distances

cutoff.od: Object of class "numeric" Cutoff values for the orthogonal distances

flag: Object of class "Uvector" The observations whose score distance is larger than cutoff.sd or whose orthogonal distance is larger than cutoff.od can be considered as outliers and receive a flag equal to zero. The regular observations receive a flag 1

**crit.pca.distances** criterion to use for computing the cutoff values for the orthogonal and score distances. Default is 0.975.

n.obs: Object of class "numeric" the number of observations

eig0: Object of class "vector" all eigenvalues

totvar0: Object of class "numeric" the total variance explained (=sum(eig0))

#### Methods

```
getCenter signature(obj = "Pca"): center of the data
```

**getScale** signature(obj = "Pca"): return the scaling applied to each variable

**getEigenvalues** signature(obj = "Pca"): the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix)

**getLoadings** signature(obj = "Pca"): returns the matrix loadings (i.e., a matrix whose columns contain the eigenvectors). The function prcomp returns this matrix in the element rotation.

getPrcomp signature(obj = "Pca"): returns an S3 object prcomp for compatibility with the functions prcomp() and princomp(). Thus the standard plots screeplot() and biplot() can be used

**getScores** signature(obj = "Pca"): returns the rotated data (the centred (and scaled if requested) data multiplied by the loadings matrix).

**getSdev** signature(obj = "Pca"): returns the standard deviations of the principal components (i.e., the square roots of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix)

plot signature(x = "Pca"): produces a distance plot (if k=rank) or distance-distance plot (if k<rank)

print signature(x = "Pca"): prints the results. The difference to the show() method is that additional parameters are possible.

**show** signature(object = "Pca"): prints the results

predict signature(object = "Pca"): calculates prediction using the results in object. An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, newdata must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order. See also predict.prcomp and predict.princomp

screeplot signature(x = "Pca"): plots the variances against the number of the principal component. See also plot.prcomp and plot.princomp 102 pca.distances

showClass("Pca")
```

pca.distances Compute score and orthogonal distances for Principal Components (objects of class 'Pca')

### **Description**

Compute score and orthogonal distances for an object (derived from)Pca-class.

## Usage

```
pca.distances(obj, data, r, crit=0.975)
```

### **Arguments**

obj an object of class (derived from) "Pca".

data The data matrix for which the "Pca" object was computed.

r rank of data

crit Criterion to use for computing the cutoff values.

### **Details**

This function calculates the score and orthogonal distances and the appropriate cutoff values for identifying outlying observations. The computed values are used to create a vector a of flags, one for each observation, identifying the outliers.

## Value

An S4 object of class derived from the virtual class Pca-class - the same object passed to the function, but with the score and orthogonal distances as well as their cutoff values and the corresponding flags appended to it.

pca.scoreplot 103

Score plot for Principal Components (objects of class 'Pca')

# Description

Produces a score plot from an object (derived from) Pca-class.

## Usage

```
pca.scoreplot(obj, i=1, j=2, main, id.n, ...)
```

## **Arguments**

| obj  | an object of class (derived from) "Pca".  |
|------|---|
| i    | First score coordinate, defaults to i=1.  |
| j    | Second score coordinate, defaults to j=2.   |
| main | The main title of the plot.   |
| id.n | Number of observations to identify by a label. If missing and the total number of observations is less or equal to 10, all observations will be labelled. |
|      | Optional arguments to be passed to the internal graphical functions.  |

PcaClassic

Principal Components Analysis

# Description

Performs a principal components analysis and returns the results as an object of class PcaClassic (aka constructor).

## Usage

## **Arguments**

| formula   | a formula with no response variable, referring only to numeric variables.   |
|-----------|---|
| data      | an optional data frame (or similar: see model.frame) containing the variables in the formula formula.   |
| subset    | an optional vector used to select rows (observations) of the data matrix x.   |
| na.action | a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The default is na.omit.   |
|           | arguments passed to or from other methods.  |
| x         | a numeric matrix (or data frame) which provides the data for the principal components analysis.   |
| k         | number of principal components to compute. If k is missing, or k = 0, the algorithm itself will determine the number of components by finding such k that $l_k/l_1>=10.E-3$ and $\Sigma_{j=1}^k l_j/\Sigma_{j=1}^r l_j>=0.8$ . It is preferable to investigate the scree plot in order to choose the number of components and then run again. Default is k=ncol(x). |
| kmax      | maximal number of principal components to compute. Default is kmax=10. If k is provided, kmax does not need to be specified, unless k is larger than 10.  |

PcaClassic-class 105

scale a value indicating whether and how the variables should be scaled to have unit

variance (only possible if there are no constant variables). If scale=FALSE (default) or scale=NULL no scaling is performed (a vector of 1s is returned in the scale slot). If scale=TRUE the data are scaled to have unit variance. Alternatively it can be a function like sd or Qn or a vector of length equal the number of columns of x. The value is passed to the underlying function and the result

returned is stored in the scale slot. Default is scale=FALSE.

signflip a logical value indicating wheather to try to solve the sign indeterminancy of the

loadings - ad hoc approach setting the maximum element in a singular vector to

be positive. Default is signflip = TRUE

crit.pca.distances

criterion to use for computing the cutoff values for the orthogonal and score

distances. Default is 0.975.

trace whether to print intermediate results. Default is trace = FALSE

### Value

An S4 object of class PcaClassic-class which is a subclass of the virtual class Pca-class.

### Note

This function can be seen as a wrapper arround prcomp() from stats which returns the results of the PCA in a class compatible with the object model for robust PCA.

PcaClassic-class Class "PcaClassic" - Principal Components Analysis

## Description

Contains the results of a classical Principal Components Analysis

#### **Objects from the Class**

Objects can be created by calls of the form new("PcaClassic", ...) but the usual way of creating PcaClassic objects is a call to the function PcaClassic which serves as a constructor.

106 PcaClassic-class

### **Slots**

```
call: Object of class "language"
center: Object of class "vector" the center of the data
scale: Object of class "vector" the scaling applied to each variable
rank: Object of class "numeric" the rank of the data matrix
loadings: Object of class "matrix" the matrix of variable loadings (i.e., a matrix whose columns
     contain the eigenvectors)
eigenvalues: Object of class "vector" the eigenvalues
scores: Object of class "matrix" the scores - the value of the projected on the space of the prin-
     cipal components data (the centred (and scaled if requested) data multiplied by the loadings
     matrix) is returned. Hence, cov(scores) is the diagonal matrix diag(eigenvalues)
k: Object of class "numeric" number of (choosen) principal components
sd: Object of class "Uvector" Score distances within the robust PCA subspace
od: Object of class "Uvector" Orthogonal distances to the robust PCA subspace
cutoff.sd: Object of class "numeric" Cutoff value for the score distances
cutoff.od: Object of class "numeric" Cutoff values for the orthogonal distances
flag: Object of class "Uvector" The observations whose score distance is larger than cutoff.sd or
     whose orthogonal distance is larger than cutoff.od can be considered as outliers and receive a
     flag equal to zero. The regular observations receive a flag 1
n.obs: Object of class "numeric" the number of observations
eig0: Object of class "vector" all eigenvalues
totvar0: Object of class "numeric" the total variance explained (=sum(eig0))
```

## **Extends**

```
Class "Pca", directly.
```

## Methods

**getQuan** signature(obj = "PcaClassic"): returns the number of observations used in the computation, i.e. n.obs

PcaCov

Robust PCA based on a robust covariance matrix

# Description

Robust PCA are obtained by replacing the classical covariance matrix by a robust covariance estimator. This can be one of the available in rrcov estimators, i.e. MCD, OGK, M or S estimator.

## Usage

```
PcaCov(x, ...)
## Default S3 method:
PcaCov(x, k = ncol(x), kmax = ncol(x), cov.control=CovControlMcd(),
    scale = FALSE, signflip = TRUE, crit.pca.distances = 0.975, trace=FALSE, ...)
## S3 method for class 'formula'
PcaCov(formula, data = NULL, subset, na.action, ...)
```

## **Arguments**

| formula     | a formula with no response variable, referring only to numeric variables.   |
|-------------|---|
| data        | an optional data frame (or similar: see $model.frame$ ) containing the variables in the formula formula.  |
| subset      | an optional vector used to select rows (observations) of the data matrix x.   |
| na.action   | a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The default is na.omit.   |
|             | arguments passed to or from other methods.  |
| х           | a numeric matrix (or data frame) which provides the data for the principal components analysis.   |
| k           | number of principal components to compute. If k is missing, or k = 0, the algorithm itself will determine the number of components by finding such k that $l_k/l_1>=10.E-3$ and $\Sigma_{j=1}^k l_j/\Sigma_{j=1}^r l_j>=0.8$ . It is preferable to investigate the scree plot in order to choose the number of components and then run again. Default is k=ncol(x). |
| kmax        | maximal number of principal components to compute. Default is kmax=10. If k is provided, kmax does not need to be specified, unless k is larger than 10.  |
| cov.control | specifies which covariance estimator to use by providing a CovControl-class object. The default is CovControlMcd-class which will indirectly call CovMcd. If cov.control=NULL is specified, the classical estimates will be used by calling CovClassic  |

.

108 PcaCov

scale a value indicating whether and how the variables should be scaled to have unit

variance (only possible if there are no constant variables). If scale=FALSE (default) or scale=NULL no scaling is performed (a vector of 1s is returned in the scale slot). If scale=TRUE the data are scaled by the estimator used to compute the covariance matrix (MCD by default). Alternatively it can be a function like sd or Qn or a vector of length equal the number of columns of x. The value is passed to the underlying function and the result returned is stored in the scale

slot. Default is scale=FALSE.

signflip a logical value indicating wheather to try to solve the sign indeterminancy of the

loadings - ad hoc approach setting the maximum element in a singular vector to

be positive. Default is signflip = TRUE

crit.pca.distances

criterion to use for computing the cutoff values for the orthogonal and score

distances. Default is 0.975.

trace whether to print intermediate results. Default is trace = FALSE

#### **Details**

PcaCov, serving as a constructor for objects of class PcaCov-class is a generic function with "formula" and "default" methods. For details see the relevant references.

### Value

An S4 object of class PcaCov-class which is a subclass of the virtual class PcaRobust-class.

PcaHubert 113

PcaHubert

ROBPCA - ROBust method for Principal Components Analysis

## **Description**

The ROBPCA algorithm was proposed by Hubert et al (2005) and stays for 'ROBust method for Principal Components Analysis'. It is resistant to outliers in the data. The robust loadings are computed using projection-pursuit techniques and the MCD method. Therefore ROBPCA can be applied to both low and high-dimensional data sets. In low dimensions, the MCD method is applied.

# Usage

```
PcaHubert(x, ...)
## Default S3 method:
PcaHubert(x, k = 0, kmax = 10, alpha = 0.75, mcd = TRUE, skew=FALSE,
maxdir=250, scale = FALSE, signflip = TRUE, crit.pca.distances = 0.975, trace=FALSE, ...)
## S3 method for class 'formula'
PcaHubert(formula, data = NULL, subset, na.action, ...)
```

# **Arguments**

| formula   | a formula with no response variable, referring only to numeric variables.   |
|-----------|---|
| data      | an optional data frame (or similar: see model.frame) containing the variables in the formula formula.   |
| subset    | an optional vector used to select rows (observations) of the data matrix x.   |
| na.action | a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The default is na.omit.   |
|           | arguments passed to or from other methods.  |
| X         | a numeric matrix (or data frame) which provides the data for the principal components analysis.   |
| k         | number of principal components to compute. If k is missing, or k = 0, the algorithm itself will determine the number of components by finding such k that $l_k/l_1>=10.E-3$ and $\sum_{j=1}^k l_j/\sum_{j=1}^r l_j>=0.8$ . It is preferable to investigate the scree plot in order to choose the number of components and then run again. Default is k=0. |
| kmax      | maximal number of principal components to compute. Default is kmax=10. If k is provided, kmax does not need to be specified, unless k is larger than 10.  |
| alpha     | this parameter measures the fraction of outliers the algorithm should resist. In MCD alpha controls the size of the subsets over which the determinant is minimized, i.e. alpha*n observations are used for computing the determinant. Allowed values are between 0.5 and 1 and the default is 0.75.  |

114 PcaHubert

mcd Logical - when the number of variables is sufficiently small, the loadings are computed as the eigenvectors of the MCD covariance matrix, hence the function CovMcd() is automatically called. The number of principal components is then taken as k = rank(x). Default is mcd=TRUE. If mcd=FALSE, the ROBPCA algorithm is always applied.

Logical - whether the adjusted outlyingness algorithm for skewed data (Hubert

et al., 2009) will be used, default is skew=FALSE.

maxdir maximal number of random directions to use for computing the outlyingness (or

the adjusted outlyingness when skew=TRUE) of the data points, see adj0utlyingness for more details. Default is maxdir=250. If the number n of observations is small all possible n\*(n-1)/2 pairs of observations are taken to generate the di-

rections.

scale a value indicating whether and how the variables should be scaled. If scale=FALSE

(default) or scale=NULL no scaling is performed (a vector of 1s is returned in the scale slot). If scale=TRUE the data are scaled to have unit variance. Alternatively it can be a function like sd or mad or a vector of length equal the number of columns of x. The value is passed to the underlying function and the result

returned is stored in the scale slot. Default is scale=FALSE.

signflip a logical value indicating wheather to try to solve the sign indeterminancy of the

loadings - ad hoc approach setting the maximum element in a singular vector to

be positive. Default is signflip = TRUE

crit.pca.distances

criterion to use for computing the cutoff values for the orthogonal and score

distances. Default is 0.975.

trace whether to print intermediate results. Default is trace = FALSE

### **Details**

skew

PcaHubert, serving as a constructor for objects of class PcaHubert-class is a generic function with "formula" and "default" methods. The calculation is done using the ROBPCA method of Hubert et al (2005) which can be described briefly as follows. For details see the relevant references.

Let n denote the number of observations, and p the number of original variables in the input data matrix X. The ROBPCA algorithm finds a robust center M (p x 1) of the data and a loading matrix P which is (p x k) dimensional. Its columns are orthogonal and define a new coordinate system. The scores T, an (n x k) matrix, are the coordinates of the centered observations with respect to the loadings:

$$T = (X - M)P$$

The ROBPCA algorithm also yields a robust covariance matrix (often singular) which can be computed as

$$S = PLP^t$$

where L is the diagonal matrix with the eigenvalues  $l_1, \ldots, l_k$ .

This is done in the following three main steps:

PcaHubert 115

**Step 1:** The data are preprocessed by reducing their data space to the subspace spanned by the n observations. This is done by singular value decomposition of the input data matrix. As a result the data are represented using at most n-1=rank(X) without loss of information.

Step 2: In this step for each data point a measure of outlyingness is computed. For this purpose the high-dimensional data points are projected on many univariate directions, each time the univariate MCD estimator of location and scale is computed and the standardized distance to the center is measured. The largest of these distances (over all considered directions) is the outlyingness measure of the data point. The h data points with smallest outlyingness measure are used to compute the covariance matrix  $\Sigma_h$  and to select the number k of principal components to retain. This is done by finding such k that  $l_k/l_1 >= 10.E - 3$  and  $\Sigma_{j=1}^k l_j/\Sigma_{j=1}^r l_j >= 0.8$  Alternatively the number of principal components k can be specified by the user after inspecting the scree plot.

**Step 3:** The data points are projected on the k-dimensional subspace spanned by the k eigenvectors corresponding to the largest k eigenvalues of the matrix  $\Sigma_h$ . The location and scatter of the projected data are computed using the reweighted MCD estimator and the eigenvectors of this scatter matrix yield the robust principal components.

## Value

An S4 object of class PcaHubert-class which is a subclass of the virtual class PcaRobust-class.

#### Note

The ROBPCA algorithm is implemented on the bases of the Matlab implementation, available as part of *LIBRA*, a *Matlab Library for Robust Analysis* to be found at www.wis.kuleuven.ac.be/stat/robust.html

Spherical Principal Components

## **Description**

The Spherical Principal Components procedure was proposed by Locantore et al., (1999) as a functional data analysis method. The idea is to perform classical PCA on the data, projected onto a unit sphere. The estimates of the eigenvectors are consistent and the procedure is extremely fast. The simulations of Maronna (2005) show that this method has very good performance.

## Usage

```
PcaLocantore(x, ...)
## Default S3 method:
PcaLocantore(x, k = ncol(x), kmax = ncol(x), delta = 0.001,
    na.action = na.fail, scale = FALSE, signflip = TRUE,
    crit.pca.distances = 0.975, trace=FALSE, ...)
## S3 method for class 'formula'
PcaLocantore(formula, data = NULL, subset, na.action, ...)
```

118 PcaLocantore

### **Arguments**

formula a formula with no response variable, referring only to numeric variables. data an optional data frame (or similar: see model.frame) containing the variables in the formula formula. subset an optional vector used to select rows (observations) of the data matrix x. na.action a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The default is na.omit. arguments passed to or from other methods. a numeric matrix (or data frame) which provides the data for the principal com-Х ponents analysis. k number of principal components to compute. If k is missing, or k = 0, the algorithm itself will determine the number of components by finding such k that  $l_k/l_1 >= 10.E - 3$  and  $\sum_{j=1}^k l_j/\sum_{j=1}^r l_j >= 0.8$ . It is preferable to investigate the scree plot in order to choose the number of components and then run again. Default is k=ncol(x). kmax maximal number of principal components to compute. Default is kmax=10. If k is provided, kmax does not need to be specified, unless k is larger than 10. delta an accuracy parameter scale a value indicating whether and how the variables should be scaled to have unit variance (only possible if there are no constant variables). If scale=FALSE (default) or scale=NULL no scaling is performed (a vector of 1s is returned in the scale slot). If scale=TRUE the data are scaled by mad. Alternatively it can be a function like sd or Qn or a vector of length equal the number of columns of x. The value is passed to the underlying function and the result returned is stored in the scale slot. Default is scale=FALSE. a logical value indicating wheather to try to solve the sign indeterminancy of the signflip loadings - ad hoc approach setting the maximum element in a singular vector to be positive. Default is signflip = TRUE crit.pca.distances criterion to use for computing the cutoff values for the orthogonal and score distances. Default is 0.975.

# Details

trace

PcaLocantore, serving as a constructor for objects of class PcaLocantore-class is a generic function with "formula" and "default" methods. For details see the relevant references.

whether to print intermediate results. Default is trace = FALSE

#### Value

An S4 object of class PcaLocantore-class which is a subclass of the virtual class PcaRobust-class.

120 PcaLocantore-class

PcaLocantore-class

Class "PcaLocantore" Spherical Principal Components

# **Description**

The Spherical Principal Components procedure was proposed by Locantore et al., (1999) as a functional data analysis method. The idea is to perform classical PCA on the the data, \ projected onto a unit sphere. The estimates of the eigenvectors are consistent and the procedure is extremly fast. The simulations of Maronna (2005) show that this method has very good performance.

# **Objects from the Class**

Objects can be created by calls of the form new("PcaLocantore", ...) but the usual way of creating PcaLocantore objects is a call to the function PcaLocantore which serves as a constructor.

### **Slots**

```
delta: Accuracy parameter
quan: Object of class "numeric" The quantile h used throughout the algorithm
call, center, scale, rank, loadings, eigenvalues, scores, k, sd, od, cutoff.sd, cutoff.od, flag, n.obs, eig0, totv
from the "Pca" class.
```

# **Extends**

```
Class "PcaRobust", directly. Class "Pca", by class "PcaRobust", distance 2.
```

### Methods

```
getQuan signature(obj = "PcaLocantore"): ...
```

# **Examples**

```
# multivariate data with outliers
library(mvtnorm)
x \leftarrow rbind(rmvnorm(200, rep(0, 6), diag(c(5, rep(1,5)))),
            rmvnorm( 15, c(0, rep(20, 5)), diag(rep(1, 6))))
# Here we calculate the principal components with PcaProj
pc <- PcaProj(x, 6)</pre>
# we could draw a biplot too:
biplot(pc)
# we could use another calculation method and another objective function, and
# maybe only calculate the first three principal components:
pc <- PcaProj(x, k=3, method="qn", CalcMethod="sphere")</pre>
biplot(pc)
# now we want to compare the results with the non-robust principal components
pc <- PcaClassic(x, k=3)</pre>
# again, a biplot for comparision:
biplot(pc)
```

PcaProj-class

Class "PcaProj" - Robust PCA using PP - Croux and Ruiz-Gazen (2005) algorithm

### **Description**

Holds the results of an approximation of the PP-estimators for PCA by a fast and simple algorithm: Croux and Ruiz-Gazen (2005) algorithm.

PcaRobust-class 123

## **Objects from the Class**

Objects can be created by calls of the form new("PcaProj", ...) but the usual way of creating PcaProj objects is a call to the function PcaProj() which serves as a constructor.

# **Slots**

call, center, scale, rank, loadings, eigenvalues, scores, k, sd, od, cutoff.sd, cutoff.od, flag, n.obs: from the "Pca" class.

## **Extends**

```
Class "PcaRobust", directly. Class "Pca", by class "PcaRobust", distance 2.
```

### Methods

```
getQuan signature(obj = "PcaProj"): ...
```

### Author(s)

Valentin Todorov <valentin.todorov@chello.at>

### References

Todorov V & Filzmoser P (2009), An Object Oriented Framework for Robust Multivariate Analysis. *Journal of Statistical Software*, **32**(3), 1–47. doi:10.18637/jss.v032.i03.

## **Examples**

```
showClass("PcaProj")
```

PcaRobust-class

Class "PcaRobust" is a virtual base class for all robust PCA classes

# **Description**

The class PcaRobust searves as a base class for deriving all other classes representing the results of the robust Principal Component Analisys methods

# **Objects from the Class**

A virtual Class: No objects may be created from it.

124 PcaRobust-class

### **Slots**

```
call: Object of class "language"
```

center: Object of class "vector" the center of the data

loadings: Object of class "matrix" the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors)

eigenvalues: Object of class "vector" the eigenvalues

scores: Object of class "matrix" the scores - the value of the projected on the space of the principal components data (the centred (and scaled if requested) data multiplied by the loadings matrix) is returned. Hence, cov(scores) is the diagonal matrix diag(eigenvalues)

k: Object of class "numeric" number of (choosen) principal components

sd: Object of class "Uvector" Score distances within the robust PCA subspace

od: Object of class "Uvector" Orthogonal distances to the robust PCA subspace

cutoff.sd: Object of class "numeric" Cutoff value for the score distances

cutoff.od: Object of class "numeric" Cutoff values for the orthogonal distances

flag: Object of class "Uvector" The observations whose score distance is larger than cutoff.sd or whose orthogonal distance is larger than cutoff.od can be considered as outliers and receive a flag equal to zero. The regular observations receive a flag 1

n.obs: Object of class "numeric" the number of observations

#### **Extends**

```
Class "Pca", directly.
```

### Methods

No methods defined with class "PcaRobust" in the signature.

plot-methods 125

| plot-methods | Methods for Function 'plot' in Package 'rrcov' |
|--------------|--|
|              |  |

# Description

Shows the Mahalanobis distances based on robust and/or classical estimates of the location and the covariance matrix in different plots. The following plots are available:

- index plot of the robust and mahalanobis distances
- distance-distance plot
- Chisquare QQ-plot of the robust and mahalanobis distances
- plot of the tolerance ellipses (robust and classic)
- Scree plot Eigenvalues comparison plot

# Usage

### **Arguments**

| x       | an object of class "Cov" or "CovRobust"   |
|---------|---|
| which   | Which plot to show? See Details for description of the options. Default is which="all".   |
| •       |   |
| classic | whether to plot the classical distances too. Default is classic=FALSE.  |
|         |   |
| ask     | logical; if 'TRUE', the user is <i>ask</i> ed before each plot, see 'par(ask=.)'. Default is ask = which=="all" && dev.interactive(). |
| cutoff  | The cutoff value for the distances.   |
| id.n    | Number of observations to identify by a label. If not supplied, the number of observations with distance larger than cutoff is used.  |
| tol     | tolerance to be used for computing the inverse see 'solve'. Default is tol = $10e-7$  |
|         | other parameters to be passed through to plotting functions.  |

126 pottery

### Methods

```
x = "Cov", y = "missing" Plot mahalanobis distances for x.

x = "CovRobust", y = "missing" Plot robust and classical mahalanobis distances for x.
```

# **Examples**

```
data(hbk)
hbk.x <- data.matrix(hbk[, 1:3])
cv <- CovClassic(hbk.x)
plot(cv)
rcv <- CovMest(hbk.x)
plot(rcv)</pre>
```

pottery

Archaic Greek Pottery data

# **Description**

The Archaic Greek Pottery data set contains data on fragments of Greek pottery which were classified into two groups according to their origin: Attic or Eritrean. Six chemical variables, metallic oxide constituents, were measured: Si, Al, Fe, Ca and Ti. The main data set consists of 13 Attic objects and 14 Eritrean ones. There is a separate data set with 13 observations which can be used as a test data set. It consists of 4 observations classified as "probably Attic" and the remaining 9 as "probably Eritrean".

# Usage

```
data(pottery)
```

# **Format**

Two data frames with 27 an 13 observations on the following 7 variables.

```
SI Si content
```

AL Al content

FE Fe content

MG Mg content

CA Ca content

TI Ti content

origin Origin - factor with two levels: Attic and Eritrean

## **Details**

The Archaic Greek Pottery data set was first published by Stern and Descoeudres (1977) and later reproduced in Cooper and Weeks (1983) for illustration of linear discriminant analysis. The data set was used by Pires and Branco (2010) for illustration of their projection pursuit approach to linear discriminant analysis.

PredictLda-class

Class "PredictLda" - prediction of "Lda" objects

### **Description**

The prediction of a "Lda" object

## **Objects from the Class**

Objects can be created by calls of the form new("PredictLda", ...) but most often by invoking 'predict' on a "Lda" object. They contain values meant for printing by 'show'

### Slots

```
classification: a factor variable containing the classification of each object posterior: a matrix containing the posterior probabilities x: matrix with the discriminant scores ct: re-classification table of the training sample
```

### Methods

```
show signature(object = "PredictLda"): Prints the results
```

Qda-class

Qda-class

Class "Qda" - virtual base class for all classic and robust QDA classes

### **Description**

The class Qda serves as a base class for deriving all other classes representing the results of classical and robust Quadratic Discriminant Analisys methods

# **Objects from the Class**

A virtual Class: No objects may be created from it.

### **Slots**

call: the (matched) function call.

prior: prior probabilities used, default to group proportions

counts: number of observations in each class

center: the group means

cov: the group covariance matrices

covinv: the inverse of the group covariance matrices

covdet: the determinants of the group covariance matrices

method: a character string giving the estimation method used

X: the training data set (same as the input parameter x of the constructor function)

grp: grouping variable: a factor specifying the class for each observation.

control: object of class "CovControl" specifying which estimate and with what estimation options to use for the group means and covariances (or NULL for classical discriminant analysis)

## Methods

predict signature(object = "Qda"): calculates prediction using the results in object. An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, newdata must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

```
show signature(object = "Qda"): prints the results
summary signature(object = "Qda"): prints summary information
```

QdaClassic

Quadratic Discriminant Analysis

# **Description**

Performs quadratic discriminant analysis and returns the results as an object of class QdaClassic (aka constructor).

# Usage

```
QdaClassic(x, ...)
## Default S3 method:
QdaClassic(x, grouping, prior = proportions, tol = 1.0e-4, ...)
```

# Arguments

x a matrix or data frame containing the explanatory variables (training set).
grouping grouping variable: a factor specifying the class for each observation.
prior probabilities, default to the class proportions for the training set.
tol tolerance
arguments passed to or from other methods.

## Value

Returns an S4 object of class QdaClassic

## Author(s)

Valentin Todorov <valentin.todorov@chello.at>

### References

Todorov V & Filzmoser P (2009), An Object Oriented Framework for Robust Multivariate Analysis. *Journal of Statistical Software*, **32**(3), 1–47. doi:10.18637/jss.v032.i03.

QdaCov-class Class "QdaCov" - Robust methods for Quadratic Discriminant Analysis

# Description

Robust quadratic discriminant analysis is performed by replacing the classical group means and withing group covariance matrices by their robust equivalents.

## **Objects from the Class**

Objects can be created by calls of the form new("QdaCov", ...) but the usual way of creating QdaCov objects is a call to the function QdaCov which serves as a constructor.

# Slots

```
call: The (matched) function call.
prior: Prior probabilities used, default to group proportions
counts: number of observations in each class
center: the group means
```

QdaRobust-class 135

```
cov: the group covariance matrices
```

covinv: the inverse of the group covariance matrices

covdet: the determinants of the group covariance matrices

method: a character string giving the estimation method used

X: the training data set (same as the input parameter x of the constructor function)

grp: grouping variable: a factor specifying the class for each observation.

control: Object of class "CovControl" specifying which estimate to use for the group means and covariances

### **Extends**

```
Class "QdaRobust", directly. Class "Qda", by class "QdaRobust", distance 2.
```

### Methods

No methods defined with class "QdaCov" in the signature.

restimate-methods 137

restimate-methods

Methods for Function estimate in Package 'rrcov'

### **Description**

Each concrete control class, like CovControlMest, CovControlOgk, etc., should implement an restimate method which will call the correponding (constructor)-function and will return the obtained S4 class, derived from CovRobust.

# Usage

```
## S4 method for signature 'CovControlMest'
restimate(obj, x, ...)
```

# **Arguments**

obj an object of class "CovControlEstimate"

x Data frame or matrix containing the data
.

... other parameters to be passed through to the estimation function.

#### Methods

- **obj = "CovControlMcd"** Compute the MCD estimates of multivariate location and scatter by callingCovMcd
- obj = "CovControlMest" Compute the constrained M-estimates of multivariate location and scatter by callingCovMest
- **obj = "CovControlOgk"** Compute the Ortogonalized Gnanadesikan-Kettenring (OGK) estimates of multivariate location and scatter by callingCovOgk

rice Rice taste data

## **Description**

The rice taste data consists of five inputs and a single output whose values are associated with subjective evaluations as follows: xl: flavor, x2: appearance, x3: taste, x4: stickiness, x5: toughness, y: overall evaluation. Sensory test data have been obtained by such subjective evaluations for 105 kinds of rice (e.g., Sasanishiki, Akita-Komachi, etc.). The data set was used by Nozaki et al. (1997) to demonstrate the high performance of a proposed for automatically generating fuzzy if-then rules from numerical data.

## Usage

```
data(rice)
```

138 salmon

### **Format**

A data frame with 105 observations on the following 6 variables:

Favor compactness

Appearance circularity

Taste distance circularity

Stickiness radius ratio

Toughness principal axis aspect ratio

Overall\_evaluation maximum length aspect ratio

### **Source**

Nozaki, K., Ishibuchi, H, and Tanaka, H. (1997) A simple but powerful heuristic method for generating fuzzy rules from numerical data *Fuzzy Sets and Systems* **86** 3 p. 251–270.

salmon

Salmon data

# Description

The salmon data contains two measurements of the growth rings on the scale of Alaskan and Canadian salmon as well as the gender of the fishes. There are 50 Alaskan-born and 50 Canadian-born salmon, and this information is coded in the variable Origin.

# Usage

data(salmon)

## **Format**

A data frame with 100 observations on the following 4 variables.

Gender female=1 and male=2

Freshwater diameter of rings for the first-year freshwater growth (hundrets of an inch)

Marine diameter of rings for the first-year marine growth (hundrets of an inch)

Origin Origin of the fish: a factor with levels Alaskan Canadian

scorePlot-methods 139

scorePlot-methods

Score plot for Principal Components (objects of class 'Pca')

# Description

Produces a score plot from an object (derived from) Pca-class.

## Usage

```
## S4 method for signature 'Pca'
scorePlot(x, i=1, j=2, ...)
```

## **Arguments**

```
    x an object of class (derived from) "Pca".
    i First score coordinate, defaults to i=1.
    j Second score coordinate, defaults to j=2.
    ... optional arguments to be passed to the internal graphical functions.
```

### **Side Effects**

a plot is produced on the current graphics device.

## Methods

**scorePlot** signature(x = Pca): Plot a scatter plot of ith against jth score of the Pca object with superimposed tollerance (0.975) ellipse. See also biplot, screeplot.

### See Also

```
Pca-class, PcaClassic, PcaRobust-class.
```

140 soil

soil

Exchangable cations in forest soil data set

# **Description**

The forest soil data set contains measurements on 58 soil pits in the Hubbard Brook Experimental Forest in north-central New Hampshire. The excavations were done in 1983 and 1986. The soil samples were analyzed for the exchangeable cations of aluminium, calcium, magnesium, potassium and sodium. The pit locations in both data sets can be classified by the type of the forest:

- 1: spruce-fir (11 samples),
- 2: high elevation hardwood (23 samples) and
- 3: low elevation hardwood (24 samples)).

Additionally the degree of logging disturbance can be considered (all 0 in the 1983 data set):

- 0: uncut forest,
- 1: cut, undisturbed by machinery and
- 2: cut, disturbed.

The observations are expressed in grams of exchangeable cations per square meter.

### Usage

data(soil)

#### **Format**

A data frame with 116 observations on the following 7 variables.

- F Type of forest
- D Degree of logging disturbance
- Al Level of the exchangable cations in Al
- Ca Level of the exchangable cations in Ca
- Mg Level of the exchangable cations in Mg
- K Level of the exchangable cations in K
- Na Level of the exchangable cations in Na

## **Examples**

```
data(soil)
soil1983 <- soil[soil$D == 0, -2]  # only 1983, remove column D (always 0)

(cc <- Linda(F^{\sim}., data=soil))
(pr <- predict(cc))
pr@classification</pre>
```

SummaryCov-class

Class "SummaryCov" - summary of "Cov" objects

## **Description**

The "Cov" object plus some additional summary information

# **Objects from the Class**

Objects can be created by calls of the form new("SummaryCov", ...), but most often by invoking 'summary' on a "Cov" object. They contain values meant for printing by 'show'.

## **Slots**

```
covobj: Object of class "Cov" evals: eigenvalues of the covariance or correlation matrix
```

## Methods

```
getCenter signature(obj = "SummaryCov"): location vector
getCov signature(obj = "SummaryCov"): covariance matrix
getDistance signature(obj = "SummaryCov"): vector of distances
getEvals signature(obj = "SummaryCov"): vector of eignevalues
isClassic signature(obj = "SummaryCov"): is the estimate a classic one
show signature(object = "SummaryCov"): display the object
```

T2.test

| T2.test | Robust Hotelling T2 test |  |
|---------|--------------------------|--|
| 12.0030 | Robust Hotelling 12 test |  |

# Description

Performs one and two sample Hotelling T2 tests as well as robust one-sample Hotelling T2 test

# Usage

```
T2.test(x, ...)
## Default S3 method:
T2.test(x, y = NULL, mu = 0, conf.level = 0.95, method=c("c", "mcd"), ...)
## S3 method for class 'formula'
T2.test(formula, data, subset, na.action, ...)
```

# Arguments

| 8          |   |
|------------|---|
| X          | a (non-empty) numeric data frame or matrix.   |
| у          | an optional (non-empty) numeric data frame or matrix.   |
| mu         | an optional (non-empty) numeric vector of data values (or a single number which will be repeated p times) indicating the true value of the mean (or difference in means if you are performing a two sample test). |
| conf.level | confidence level of the interval  |
| method     | the method to be used - 'c' for sample mean and covariance matrix and 'mcd' for minimum covariance determinant estimator. A two-sample MCD based T2-test is not yet implemented.                                  |
| formula    | a formula of the form 1hs $\sim$ rhs where 1hs is a numeric data frame or matrix giving the observations and rhs a factor with two levels giving the corresponding groups.  |
| data       | an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).                                     |
| subset     | an optional vector specifying a subset of observations to be used (currently not used)  |
| na.action  | a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action") (currently only "na.rm" used)   |
|            | further arguments to be passed to or from methods.  |

# **Details**

The formula interface is only applicable for the two-sample tests.

T2.test 147

#### Value

statistic

null.value

A list with class "htest" containing the following components:

the value of the T2-statistic.

parameter the degrees of freedom for the T2-statistic.

p.value the p-value for the test.

conf.int a confidence interval for the mean vector appropriate to the specified alternative hypothesis.

estimate the estimated mean vector or vectors depending on whether it was a one-sample test or a two-sample test.

the specified hypothesized value of the mean or mean difference depending on

whether it was a one-sample test or a two-sample test.

alternative a character string describing the alternative hypothesis.

method a character string indicating what type of T2-test was performed.

data.name a character string giving the name(s) of the data.

un86

United Nations Data - 1986

# Description

This data set consists of seven socioeconomic variables observed for 73 countries.

## Usage

data(un86)

#### **Format**

A data frame with 73 observations on the following 7 variables.

POP Total population in milions

MOR Number of infant deaths per thousand births

CAR Number of motorized vehicles per hundred inhabitants

DR Number of medical doctors per thousand inhabitants

GNP Gross national product per inhabitant in thousands of US dollars

DEN Density in inhabitants per square kilometer

TB Trade balance, defined as total exports/(total exports + total imports)

# Details

The data set is from World Statistics in Brief, Number 10, a 1986 UN publication. It was used in Daigle et al. (1992) to illustrate a robust biplot method.

#### **Source**

wages 149

wages

Wages and Hours

## **Description**

The data are from a national sample of 6000 households with a male head earning less than USD 15,000 annually in 1966. The data were clasified into 39 demographic groups for analysis. The study was undertaken in the context of proposals for a guaranteed annual wage (negative income tax). At issue was the response of labor supply (average hours) to increasing hourly wages. The study was undertaken to estimate this response from available data.

## Usage

data(wages)

## **Format**

A data frame with 39 observations on the following 10 variables:

HRS Average hours worked during the year

RATE Average hourly wage (USD)

ERSP Average yearly earnings of spouse (USD)

ERNO Average yearly earnings of other family members (USD)

NEIN Average yearly non-earned income

ASSET Average family asset holdings (Bank account, etc.) (USD)

AGE Average age of respondent

DEP Average number of dependents

RACE Percent of white respondents

SCHOOL Average highest grade of school completed

Wilks.test

Classical and Robust One-way MANOVA: Wilks Lambda

## **Description**

Classical and Robust One-way MANOVA: Wilks Lambda

## Usage

#### **Arguments**

formula

A formula of the form groups  $\sim x1 + x2 + \dots$  That is, the response is the grouping factor and the right hand side specifies the (non-factor) variables.

Wilks.test 151

| data          | Data frame from which variables specified in formula are to be taken.  |
|---------------|--|
| х             | (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.  |
| grouping      | grouping variable - a factor specifying the class for each observation (required if no formula argument is given.)   |
| subset        | An index vector specifying the cases to be used.   |
| na.action     | A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is na.omit, which leads to rejection of cases with missing values on any required variable. |
| method        | "c" for standard estimators of the mean and variance, "mcd" for MCD estimators of mean and variances and "rank" for rank based wilks' lambda as proposed by Nath and Pavur (1985).   |
| approximation | "Bartlett" for Bartlett approximation (default), "Rao" for rao approximation (only for method="c") and "empirical" for simulated empirical distribution.   |
| xd            | multiplication factor for the approximate distribution of the robust Lambda statistic. If xd=NULL the factor will computed by simulation and will be returned in the value (see Details)                                   |
| xq            | the degrees of freedom for the approximate $\chi^2$ distribution of the robust Lambda statistic. If xq=NULL the degrees of freedom will computed by simulation and will be returned in the value (see Details)             |
| xfn           | the empirical distribution function. If xfn=NULL the empirical function will be estimated by simulation and will be returned in the value (see Details)  |
| xwl           | the simulated values of the robust statistic. If xwl=NULL the simulation will be performed and the calculated result will be returned in the value (see Details)   |
| nrep          | number of trials for the simulations for computing the multiplication factor xd and the degrees of freedom xq. Default is nrep=3000.   |
| trace         | whether to print intermediate results. Default is trace = FALSE  |
| •••           | arguments passed to or from other methods.   |

## **Details**

The classical Wilks' Lambda statistic for testing the equality of the group means of two or more groups is modified into a robust one through substituting the classical estimates by the highly robust and efficient reweighted MCD estimates, which can be computed efficiently by the FAST-MCD algorithm - see CovMcd. An approximation for the finite sample distribution of the Lambda statistic is obtained, based on matching the mean and variance of a multiple of an  $\chi^2$  distribution which are computed by simultaion.

## Value

A list with class "htest" containing the following components:

statistic the value of the Wilks' Lambda statistic.

parameter The corresponding approximation of the Wilks' lambda statistic and the degrees

of freedom.

Wilks.test

method a character string indicating what type of test was performed.

data.name a character string giving the name of the data.

xd multiplication factor for the approximate distribution of the robust Lambda statis-

tic.

xq the degrees of freedom for the approximate  $\chi^2$  distribution of the robust Lambda

statistic.

#### Note

This function may be called giving either a formula and optional data frame, or a matrix and grouping factor as the first two arguments. All other arguments are optional.

wolves

Skull dimensions of the wolf Canis lupus L.

## **Description**

A data set containing skull morphometric measurements on Rocky Mountain and Arctic wolves (*Canis Lupus L.*). The tdata are published in Morrison (1990), originally from Jolicoeur (1959).

## Usage

```
data(wolves)
```

#### Format

A data frame with 25 rows and 12 variables. The variables are as follows (all measurements are in milimeters):

- class: a factor presenting the combinations of location and sex. The levels are arf arm rmf and rmm
- location: a factor with levels ar=Arctic, rm=Rocky Mountain
- sex: a factor with levels f=female, m=male
- x1: palatal length
- x2: postpalatal length
- x3: zygomatic width

154 wolves

- x4: palatal width outside first upper molars
- x5: palatal width inside second upper molars
- x6: postglenoid foramina width
- x7: interorbital width
- x8: braincase width
- x9: crown length
